EVALUATION KIT AVAILABLE

# 1.8V, 12-Bit, 210Msps ADC for Broadband Applications

## General Description

The MAX1214 is a monolithic, 12-bit, 210Msps analog-to-digital converter (ADC) optimized for outstanding dynamic performance at high-IF frequencies up to 300MHz. The product operates with conversion rates up to 210Msps while consuming only 820mW.

At 210Msps and an input frequency up to 250MHz, the MAX1214 achieves a spurious-free dynamic range (SFDR) of 77.2dBc. Its excellent signal-to-noise ratio (SNR) of 66dB at 10MHz remains flat (within 2dB) for input tones up to 300MHz. This ADC yields an excellent low noise floor of -67.6dBFS, which makes it ideal for wideband applications such as cable-head end receivers and power-amplifier predistortion in cellular base-station transceivers.

The MAX1214 requires a single 1.8V supply. The analog input is designed for either differential or single-ended operation and can be AC- or DC-coupled. The ADC also features a selectable on-chip divide-by-2 clock circuit, which allows the user to apply clock frequencies as high as 340MHz. This helps to reduce the phase noise of the input clock source. A low-voltage differential signal (LVDS) sampling clock is recommended for best performance. The converter's digital outputs are LVDS compatible and the data format can be selected to be either two's complement or offset binary.

The MAX1214 is available in a 68-pin QFN package with exposed paddle (EP) and is specified over the industrial (-40°C to +85°C) temperature range.

See the *Pin-Compatible Versions* table for a complete selection of 8-bit, 10-bit, and 12-bit high-speed DACs in this family (with and without input buffers).

## Applications

Base-Station Power-Amplifier Linearization

Cable-Head End Receivers

Wireless and Wired Broadband Communication

Communications Test Equipment

Radar and Satellite Subsystems

## Features

- **210Msps Conversion Rate**
- **Low Noise Floor of -67.6dBFS**
- **Excellent Low-Noise Characteristics**
  **SNR = 65.6dB at $f_{IN}$ = 100MHz**
  **SNR = 65dB at $f_{IN}$ = 250MHz**
- **Excellent Dynamic Range**
  **SFDR = 74.2dBc at $f_{IN}$ = 100MHz**
  **SFDR = 77.2dBc at $f_{IN}$ = 250MHz**
- **59.5dB NPR for $f_{NOTCH}$ = 28.8MHz and a Noise Bandwidth of 50MHz**
- **Single 1.8V Supply**
- **820mW Power Dissipation at $f_{SAMPLE}$ = 210MHz and $f_{IN}$ = 100MHz**
- **On-Chip Track-and-Hold Amplifier**
- **Internal 1.23V-Bandgap Reference**
- **On-Chip Selectable Divide-by-2 Clock Input**
- **LVDS Digital Outputs with Data Clock Output**
- **MAX1214 EV Kit Available**

## Ordering Information

| PART | TEMP RANGE | PIN-PACKAGE |
|---|---|---|
| MAX1214EGK-D | -40°C to +85°C | 68 QFN-EP* |
| MAX1214EGK+D | -40°C to +85°C | 68 QFN-EP* |

**EP = Exposed paddle.*
*+Denotes lead-free package.*
D = *Dry pack.*

## Pin-Compatible Versions

| PART | RESOLUTION (BITS) | SPEED GRADE (Msps) | ON-CHIP BUFFER |
|---|---|---|---|
| MAX1121 | 8 | 250 | Yes |
| MAX1122 | 10 | 170 | Yes |
| MAX1123 | 10 | 210 | Yes |
| MAX1124 | 10 | 250 | Yes |
| MAX1213 | 12 | 170 | Yes |
| MAX1215 | 12 | 250 | Yes |
| MAX1213N | 12 | 170 | No |
| MAX1214N | 12 | 210 | No |
| MAX1215N | 12 | 250 | No |

***Pin Configuration appears at end of data sheet.***

# 1.8V, 12-Bit, 210Msps ADC for Broadband Applications

## ABSOLUTE MAXIMUM RATINGS

$AV_{CC}$ to AGND .....-0.3V to +2.1V
$OV_{CC}$ to OGND .....-0.3V to +2.1V
$AV_{CC}$ to $OV_{CC}$ .....-0.3V to +2.1V
AGND to OGND .....-0.3V to +0.3V
INP, INN to AGND.....-0.3V to ($AV_{CC}$ + 0.3V)
All Digital Inputs to AGND.....-0.3V to ($AV_{CC}$ + 0.3V)
REFIO, REFADJ to AGND.....-0.3V to ($AV_{CC}$ + 0.3V)
All Digital Outputs to OGND.....-0.3V to ($OV_{CC}$ + 0.3V)

Continuous Power Dissipation ($T_A$ = +70°C, multi-layer board)
68-Pin QFN-EP (derate 41.7mW/°C above +70°C).....3333mW/°C
Operating Temperature Range .....-40°C to +85°C
Junction Temperature .....+150°C
Storage Temperature Range .....-60°C to +150°C
Maximum Current into Any Pin .....±50mA
Lead Temperature (soldering,10s) .....+300°C

*Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.*

## ELECTRICAL CHARACTERISTICS

($AV_{CC}$ = $OV_{CC}$ = 1.8V, AGND = OGND = 0, $f_{SAMPLE}$ = 210MHz, differential sine-wave clock input drive, 0.1µF capacitor on REFIO, internal reference, digital output pins differential $R_L$ = 100Ω ±1%, $T_A$ = $T_{MIN}$ to $T_{MAX}$, unless otherwise noted. Typical values are at $T_A$ = +25°C.) (Note 1)

## Pin Description

| PIN | NAME | FUNCTION |
|---|---|---|
| 1, 6, 11–14, 20, 25, 62, 63, 65 | $AV_{CC}$ | Analog Supply Voltage. Bypass each pin with a parallel combination of 0.1µF and 0.22µF capacitors for best decoupling results. |
| 2, 5, 7, 10, 15, 16, 18, 19, 21, 24, 64, 66, 67 | AGND | Analog Converter Ground |
| 3 | REFIO | Reference Input/Output. With REFADJ pulled high, this I/O port allows an external reference source to be connected to the MAX1214. With REFADJ pulled low, the internal 1.23V bandgap reference is active. |
| 4 | REFADJ | Reference Adjust Input. REFADJ allows for FSR adjustments by placing a resistor or trim potentiometer between REFADJ and AGND (decreases FSR) or REFADJ and REFIO (increases FSR). If REFADJ is connected to $AV_{CC}$, the internal reference can be overdriven with an external source connected to REFIO. If REFADJ is connected to AGND, the internal reference is used to determine the FSR of the data converter. |
| 8 | INP | Positive Analog Input Terminal. Internally self-biased to 1.365V. |
| 9 | INN | Negative Analog Input Terminal. Internally self-biased to 1.365V. |
| 17 | CLKDIV | Clock Divider Input. This LVCMOS-compatible input controls with which speed the converter's digital outputs are updated. CLKDIV has an internal pulldown resistor.<br>CLKDIV = 0: ADC updates digital outputs at one-half the input clock rate.<br>CLKDIV = 1: ADC updates digital outputs at input clock rate. |
| 22 | CLKP | True Clock Input. This input ideally requires an LVPECL-compatible input level to maintain the converter's excellent performance. Internally self-biased to 1.15V. |
| 23 | CLKN | Complementary Clock Input. This input ideally requires an LVPECL-compatible input level to maintain the converter's excellent performance. Internally self-biased to 1.15V. |
| 26, 45, 61 | OGND | Digital Converter Ground. Ground connection for digital circuitry and output drivers. |
| 27, 28, 41, 44, 60 | $OV_{CC}$ | Digital Supply Voltage. Bypass with a 0.1µF capacitor for best decoupling results. |
| 29 | D0N | Complementary Output Bit 0 (LSB) |
| 30 | D0P | True Output Bit 0 (LSB) |
| 31 | D1N | Complementary Output Bit 1 |
| 32 | D1P | True Output Bit 1 |
| 33 | D2N | Complementary Output Bit 2 |
| 34 | D2P | True Output Bit 2 |
| 35 | D3N | Complementary Output Bit 3 |
| 36 | D3P | True Output Bit 3 |

## Pin Description (continued)

| PIN | NAME | FUNCTION |
|---|---|---|
| 37 | D4N | Complementary Output Bit 4 |
| 38 | D4P | True Output Bit 4 |
| 39 | D5N | Complementary Output Bit 5 |
| 40 | D5P | True Output Bit 5 |
| 42 | DCLKN | Complementary Clock Output. This output provides an LVDS-compatible output level and can be used to synchronize external devices to the converter clock. |
| 43 | DCLKP | True Clock Output. This output provides an LVDS-compatible output level and can be used to synchronize external devices to the converter clock. |
| 46 | D6N | Complementary Output Bit 6 |
| 47 | D6P | True Output Bit 6 |
| 48 | D7N | Complementary Output Bit 7 |
| 49 | D7P | True Output Bit 7 |
| 50 | D8N | Complementary Output Bit 8 |
| 51 | D8P | True Output Bit 8 |
| 52 | D9N | Complementary Output Bit 9 |
| 53 | D9P | True Output Bit 9 |
| 54 | D10N | Complementary Output Bit 10 |
| 55 | D10P | True Output Bit 10 |
| 56 | D11N | Complementary Output Bit 11 (MSB) |
| 57 | D11P | True Output Bit 11 (MSB) |
| 58 | ORN | Complementary Output for Out-of-Range Control Bit. If an out-of-range condition is detected, bit ORN flags this condition by transitioning low. |
| 59 | ORP | True Output for Out-of-Range Control Bit. If an out-of-range condition is detected, bit ORP flags this condition by transitioning high. |
| 68 | $\overline{T}$/B | Two's Complement or Binary Output Format Selection. This LVCMOS-compatible input controls the digital output format of the MAX1214. $\overline{T}$/B has an internal pulldown resistor.<br>$\overline{T}$/B = 0: Two's complement output format.<br>$\overline{T}$/B = 1: Binary output format. |
| — | EP | Exposed Paddle. The exposed paddle is located on the backside of the chip and must be connected to analog ground for optimum performance. |

# 1.8V, 12-Bit, 210Msps ADC for Broadband Applications

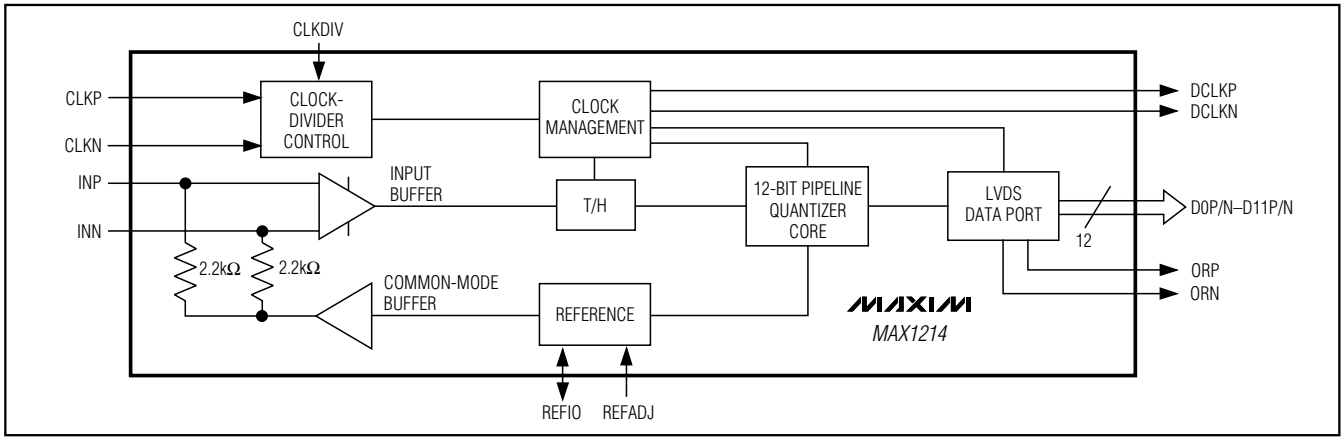

*Figure 1. MAX1214 Block Diagram*

## Detailed Description—Theory of Operation

The MAX1214 uses a fully differential pipelined architecture that allows for high-speed conversion, optimized accuracy, and linearity while minimizing power consumption and die size.

Both positive (INP) and negative/complementary analog input terminals (INN) are centered around a 1.365V common-mode voltage, and accept a differential analog input voltage swing of $\pm V_{FS} / 4$ each, resulting in a typical $1.454V_{P-P}$ differential full-scale signal swing. Inputs INP and INN are buffered prior to entering each T/H stage and are sampled when the differential sampling clock signal transitions high.

Each pipeline converter stage converts its input voltage to a digital output code. At every stage, except the last, the error between the input voltage and the digital output code is multiplied and passed along to the next pipeline stage. Digital error correction compensates for ADC comparator offsets in each pipeline stage and ensures no missing codes. The result is a 12-bit parallel digital output word in user-selectable two's-complement or offset binary output formats with LVDS-compatible output levels. See Figure 1 for a more detailed view of the MAX1214 architecture.

### Analog Inputs (INP, INN)

INP and INN are the fully differential inputs of the MAX1214. Differential inputs usually feature good rejection of even-order harmonics, which allows for enhanced AC performance as the signals are progressing through the analog stages. The MAX1214 analog inputs are self-biased at a 1.365V common-mode voltage and allow a $1.454V_{P-P}$ differential input voltage swing (Figure 2). Both inputs are self-biased through

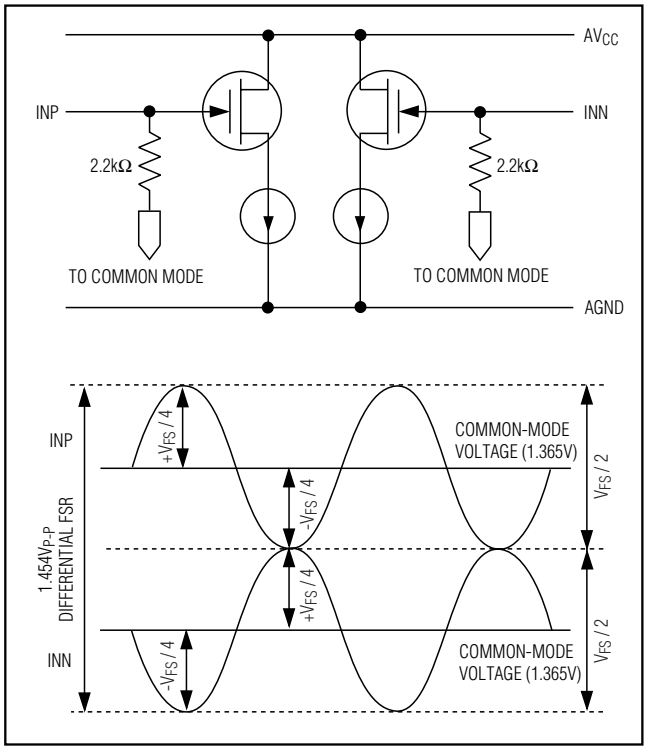

*Figure 2. Simplified Analog Input Architecture and Allowable Input Voltage Range*

2kΩ resistors, resulting in a typical differential input resistance of 4kΩ. It is recommended to drive the analog inputs of the MAX1214 in AC-coupled configuration to achieve best dynamic performance. See the *Transformer-Coupled, Differential Analog Input Drive* section for a detailed discussion of this configuration.

### On-Chip Reference Circuit

The MAX1214 features an internal 1.23V bandgap reference circuit (Figure 3), which in combination with an internal reference-scaling amplifier determines the FSR of the MAX1214. Bypass REFIO with a 0.1µF capacitor to AGND. To compensate for gain errors or increase the ADC's FSR, the voltage of this bandgap reference can be indirectly adjusted by adding an external resistor (e.g., 100kΩ trim potentiometer) between REFADJ and AGND or REFADJ and REFIO. See the *Applications Information* section for a detailed description of this process.

To disable the internal reference, connect REFADJ to $AV_{CC}$. In this configuration, an external, stable reference must be applied to REFIO to set the converter's full scale. To enable the internal reference, connect REFADJ to AGND.

### Clock Inputs (CLKP, CLKN)

Designed for a differential LVDS clock input drive, it is recommended to drive the clock inputs of the MAX1214 with an LVDS- or PECL-compatible clock to achieve the best dynamic performance. The clock signal source must be a high-quality, low phase noise with fast edge rates to avoid any degradation in the noise performance of the ADC. The clock inputs (CLKP, CLKN) are internally biased to 1.15V, accept a typical $0.5V_{P-P}$ differential signal swing, and are usually driven in AC-coupled configuration. See the *Differential, AC-Coupled PECL-Compatible Clock Input* section for more circuit details on how to drive CLKP and CLKN appropriately. Although not recommended, the clock inputs also accept a single-ended input signal.

The MAX1214 also features an internal clock-management circuit (duty-cycle equalizer) that ensures the clock signal applied to inputs CLKP and CLKN is processed to provide a 50% duty-cycle clock signal that desensitizes the performance of the converter to variations in the duty cycle of the input clock source. Note that the clock duty-cycle equalizer cannot be turned off externally and requires a minimum clock frequency of >20MHz to work appropriately and according to data sheet specifications.

### Data Clock Outputs (DCLKP, DCLKN)

The MAX1214 features a differential clock output, which can be used to latch the digital output data with an external latch or receiver. Additionally, the clock output can be used to synchronize external devices (e.g., FPGAs) to the ADC. DCLKP and DCLKN are differential outputs with LVDS-compatible voltage levels. There is a 4.31ns delay time between the rising (falling) edge of CLKP (CLKN) and the rising edge of DCLKP (DCLKN). See Figure 4 for timing details.

### Divide-by-2 Clock Control (CLKDIV)

The MAX1214 offers a clock control line (CLKDIV), which supports the reduction of clock jitter in a system. Connect CLKDIV to OGND to enable the ADC's internal divide-by-2 clock divider. Data is now updated at one-half the ADC's input clock rate. CLKDIV has an internal pulldown resistor and can be left open for applications that require this divide-by-2 mode. Connecting CLKDIV to $OV_{CC}$ disables the divide-by-2 mode.

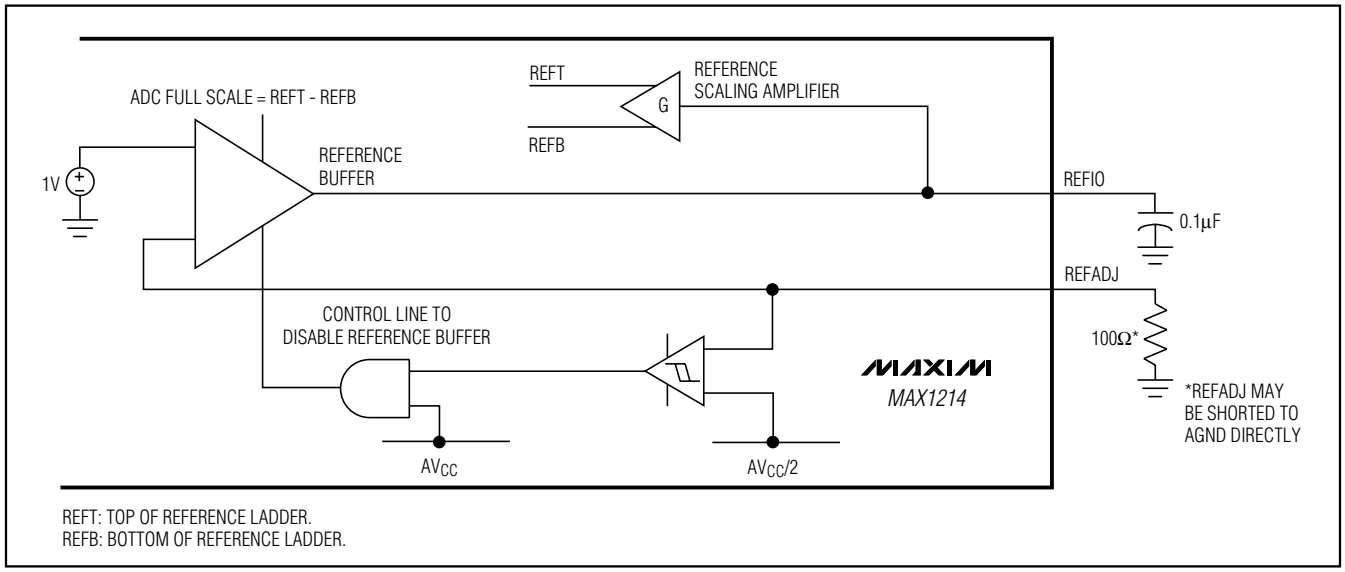

*Figure 3. Simplified Reference Architecture*

# 1.8V, 12-Bit, 210Msps ADC for Broadband Applications

### System Timing Requirements

Figure 4 depicts the relationship between the clock input and output, analog input, sampling event, and data output. The MAX1214 samples on the rising (falling) edge of CLKP (CLKN). Output data is valid on the next rising (falling) edge of the DCLKP (DCLKN) clock, but has an internal latency of 11 clock cycles.

### Digital Outputs (D0P/N–D11P/N, DCLKP/N, ORP/N) and Control Input $\overline{T}$/B

Digital outputs D0P/N–D11P/N, DCLKP/N, and ORP/N are LVDS compatible, and data on D0P/N–D11P/N is presented in either binary or two's-complement format (Table 1). The $\overline{T}$/B control line is an LVCMOS-compatible input, which allows the user to select the desired output format. Pulling $\overline{T}$/B low outputs data in two's complement and pulling it high presents data in offset binary format on the 12-bit parallel bus. $\overline{T}$/B has an internal pulldown resistor and may be left unconnected in applications using only two's-complement output format. All LVDS outputs provide a typical voltage swing of 0.325V around a common-mode voltage of 1.15V, and must be terminated at the far end of each transmission line pair (true and complementary) with 100Ω. The LVDS outputs are powered from a separate power supply, which can be operated between 1.7V and 1.9V.

The MAX1214 offers an additional differential output pair (ORP, ORN) to flag out-of-range conditions, where out-of-range is above positive or below negative full scale. An out-of-range condition is identified with ORP (ORN) transitioning high (low).

**Note:** Although a differential LVDS output architecture reduces single-ended transients to the supply and ground planes, capacitive loading on the digital outputs should still be kept as low as possible. Using LVDS buffers on the digital outputs of the ADC when driving larger loads may improve overall performance and reduce system-timing constraints.

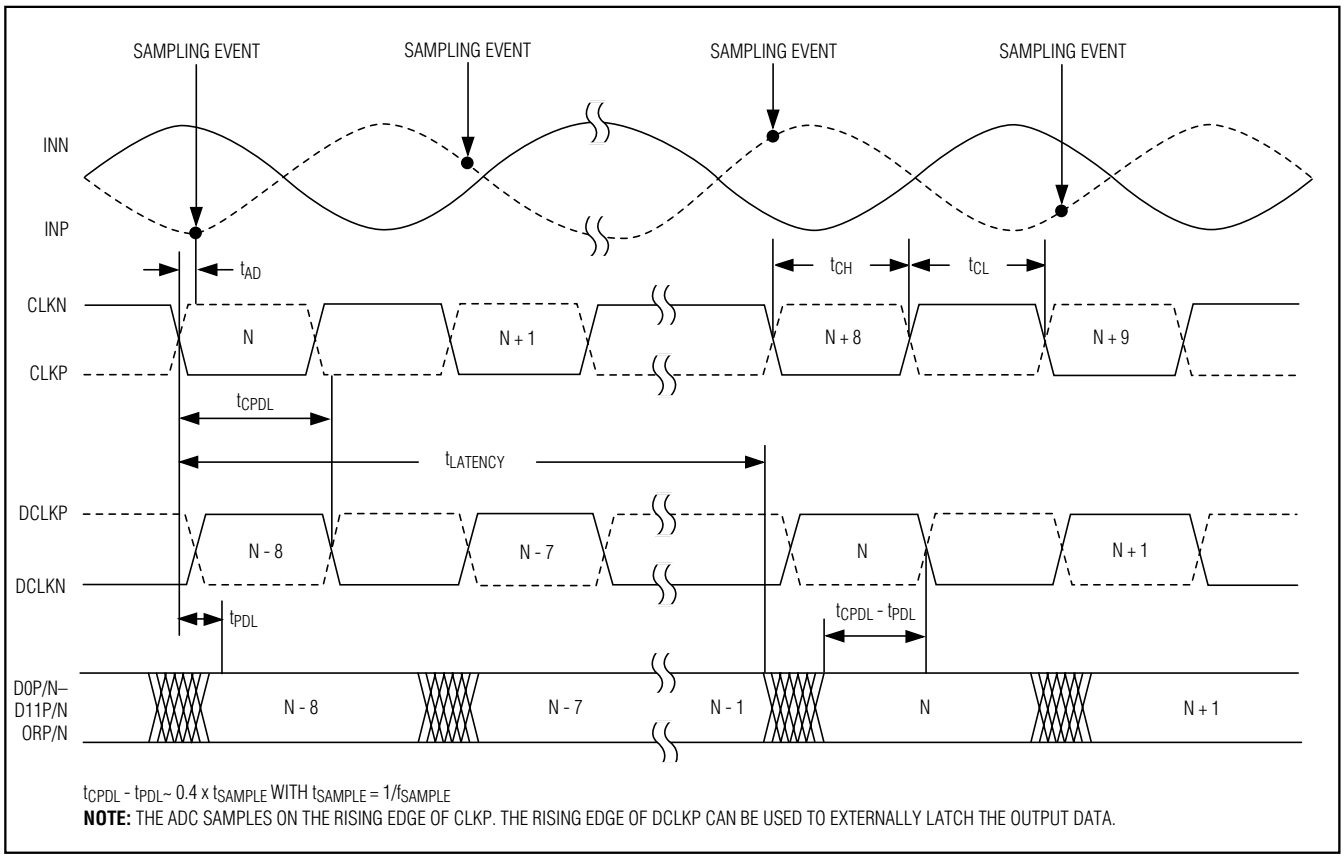

*Figure 4. System and Output Timing Diagram*

**Table 1. MAX1214 Digital Output Coding**

| INP ANALOG INPUT VOLTAGE LEVEL | INN ANALOG INPUT VOLTAGE LEVEL | OUT-OF-RANGE ORP (ORN) | BINARY DIGITAL OUTPUT CODE (D11P/N–D0P/N) | TWO'S COMPLEMENT DIGITAL OUTPUT CODE (D11P/N–D0P/N) |
|---|---|---|---|---|
| > $V_{CM}$ + $V_{FS}$ / 4 | < $V_{CM}$ - $V_{FS}$ / 4 | 1 (0) | 1111 1111 1111 (exceeds +FS, OR set) | 0111 1111 1111 (exceeds +FS, OR set) |

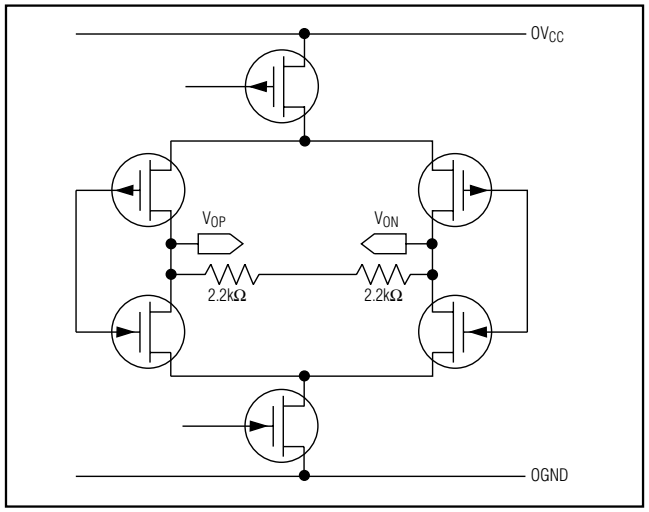

*Figure 5. Simplified LVDS Output Architecture*

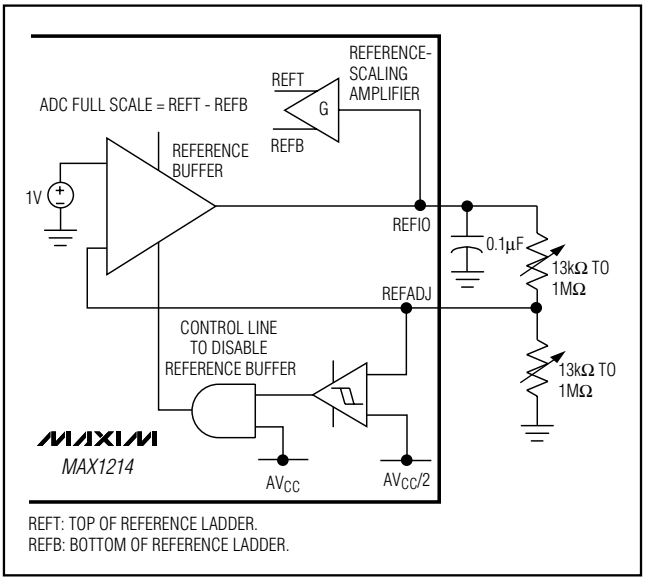

*Figure 6a. Circuit Suggestions to Adjust the ADC's Full-Scale Range*

## Applications Information

### FSR Adjustments Using the Internal Bandgap Reference

The MAX1214 supports a full-scale adjustment range of 10% (±5%). To decrease the full-scale signal range, an external resistor value ranging from 13kΩ to 1MΩ may be added between REFADJ and AGND. A similar approach can be taken to increase the ADC's full-scale range FSR. Adding a variable resistor, potentiometer, or predetermined resistor value between REFADJ and REFIO increases the FSR of the data converter. Figure 6a shows the two possible configurations and their impact on the overall full-scale range adjustment of the MAX1214. Do not use resistor values of less than 13kΩ to avoid instability of the internal gain regulation loop for the bandgap reference. See Figure 6b for the results of the adjustment range for a selection of resistors used to trim the full-scale range of the MAX1214.

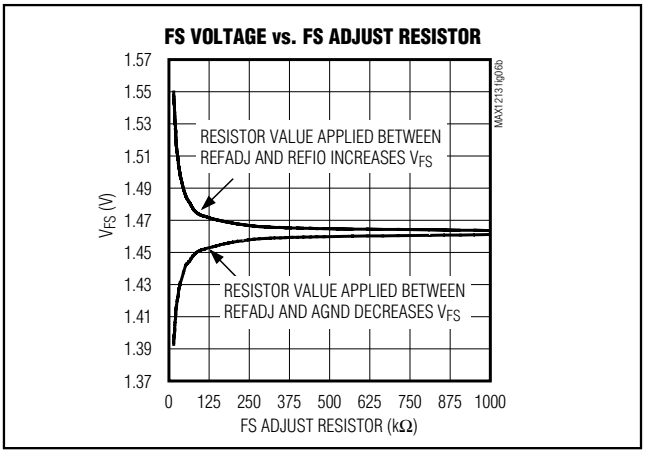

*Figure 6b. FS Adjustment Range vs. FS Adjustment Resistor*

# 1.8V, 12-Bit, 210Msps ADC for Broadband Applications

### Differential, AC-Coupled, LVPECL-Compatible Clock Input

The MAX1214 dynamic performance depends on the use of a very clean clock source. The phase noise floor of the clock source has a negative impact on the SNR performance. Spurious signals on the clock signal source also affect the ADC's dynamic range. The preferred method of clocking the MAX1214 is differentially with LVDS- or LVPECL-compatible input levels. The fast data transition rates of these logic families minimize the clock-input circuitry's transition uncertainty, thereby improving the SNR performance. To accomplish this, a 50Ω reverse-terminated clock signal source with low phase noise is AC-coupled into a fast differential receiver such as the MC100LVEL16D (Figure 7). The receiver produces the necessary LVPECL output levels to drive the clock inputs of the data converter.

### Transformer-Coupled, Differential Analog Input Drive

In general, the MAX1214 provides the best SFDR and THD with fully differential input signals and it is not recommended to drive the ADC inputs in single-ended configuration. In differential input mode, even-order harmonics are usually lower since INP and INN are balanced, and each of the ADC inputs only requires half the signal swing compared to a single-ended configuration. Wideband RF transformers provide an excellent solution to convert a single-ended signal to a fully differential signal, required by the MAX1214 to reach its optimum dynamic performance.

A secondary-side termination of a 1:1 transformer (e.g., Mini-Circuit's ADT1-1WT) into two separate 24.9Ω ±1% resistors (use tight resistor tolerances to minimize effects of imbalance; 0.5% would be an ideal choice) placed between top/bottom and center tap of the transformer is recommended to maximize the ADC's dynamic range. This configuration optimizes THD and SFDR performance of the ADC by reducing the effects of transformer parasitics. However, the source impedance combined with the shunt capacitance provided by a PCB and the ADC's parasitic capacitance limit the ADC's full-power input bandwidth to approximately 600MHz.

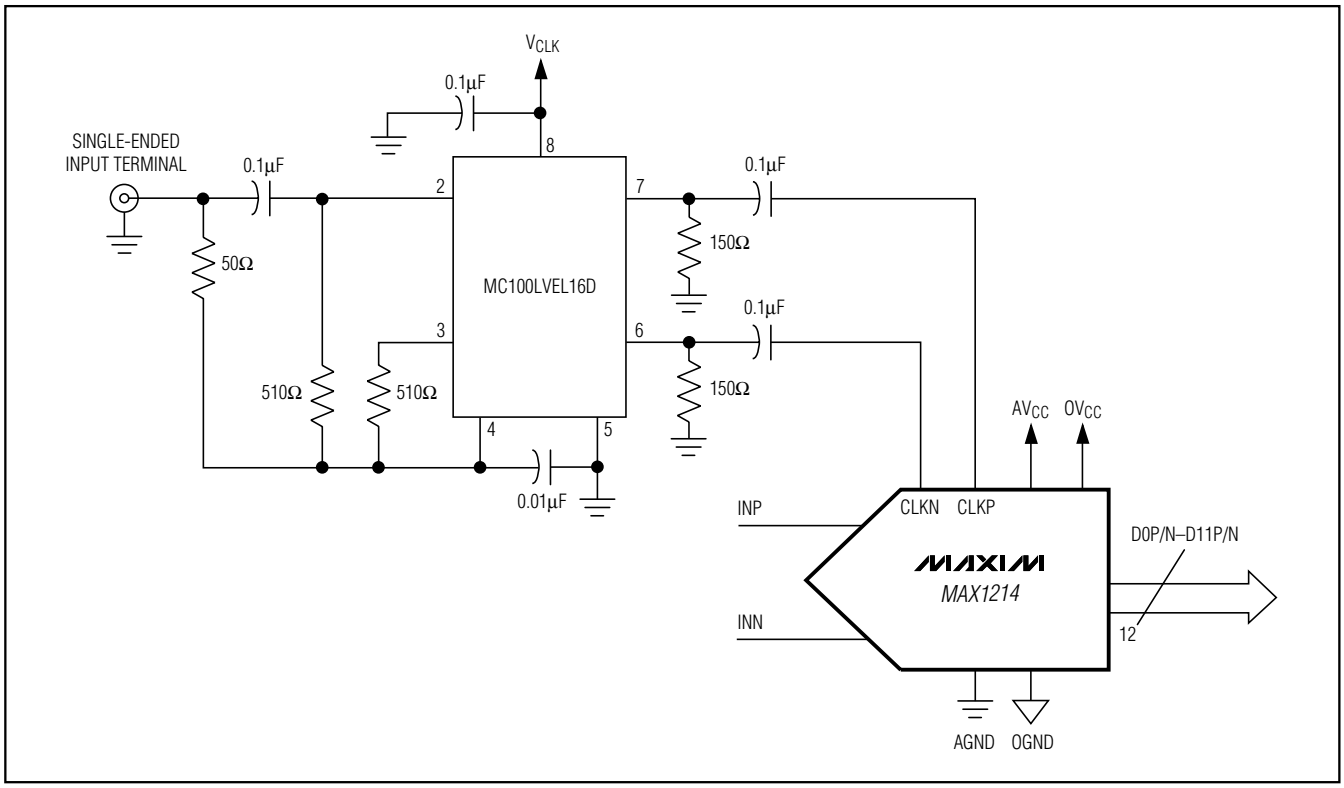

*Figure 7. Differential, AC-Coupled, LVPECL-Compatible Clock Input Configuration*

To further enhance THD and SFDR performance at high input frequencies (>100MHz), a second transformer (Figure 8) should be placed in series with the single-ended-to-differential conversion transformer. This transformer reduces the increase of even-order harmonics at high frequencies.

### Single-Ended, AC-Coupled Analog Inputs

Although not recommended, the MAX1214 can be used in single-ended mode (Figure 9). Analog signals can be AC-coupled to the positive input INP through a 0.1µF capacitor and terminated with a 49.9Ω resistor to AGND. The negative input should be reverse terminated with 49.9Ω resistors and AC-grounded with a 0.1µF capacitor.

## Grounding, Bypassing, and Board Layout Considerations

The MAX1214 requires board layout design techniques suitable for high-speed data converters. This ADC provides separate analog and digital power supplies. The analog and digital supply voltage pins accept 1.7V to 1.9V input voltage ranges. Although both supply types can be combined and supplied from one source, it is recommended to use separate sources to cut down on performance degradation caused by digital switching currents, which can couple into the analog supply network. Isolate analog and digital supplies ($AV_{CC}$ and $OV_{CC}$) where they enter the PCB with separate networks of ferrite beads and capacitors to their corresponding grounds (AGND, OGND).

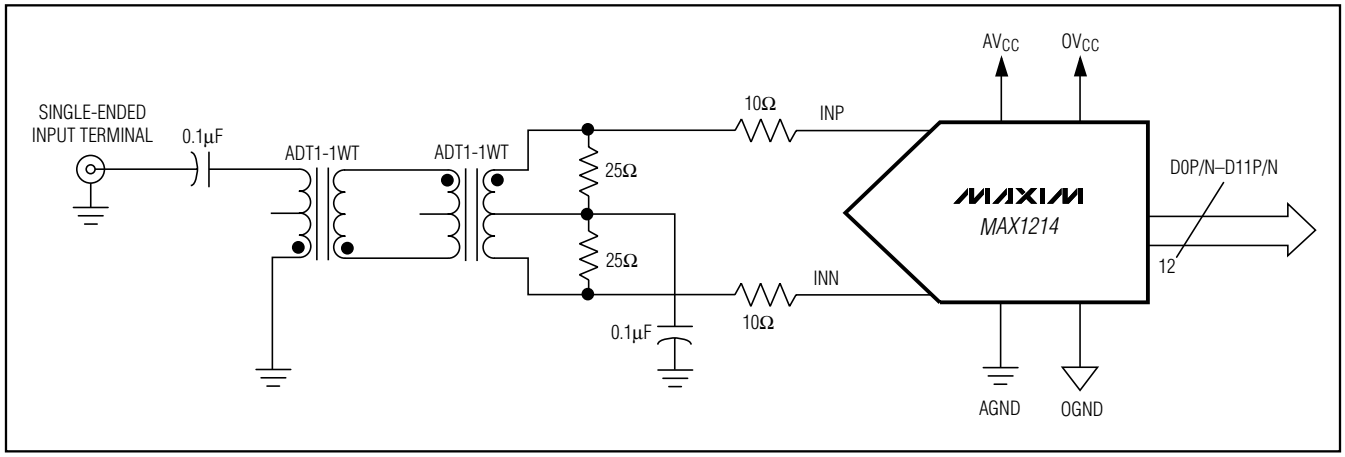

*Figure 8. Analog Input Configuration with Back-to-Back Transformers and Secondary-Side Termination*

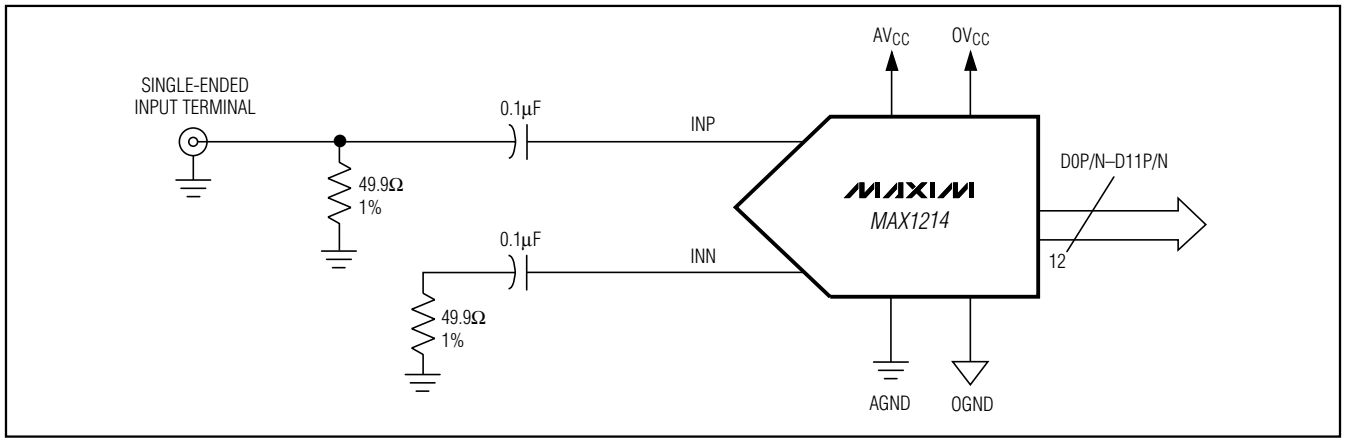

*Figure 9. Single-Ended AC-Coupled Analog Input Configuration*

# 1.8V, 12-Bit, 210Msps ADC for Broadband Applications

To achieve optimum performance, provide each supply with a separate network of a 47µF tantalum capacitor and parallel combinations of 10µF and 1µF ceramic capacitors. Additionally, the ADC requires each supply pin to be bypassed with separate 0.1µF ceramic capacitors (Figure 10). Locate these capacitors directly at the ADC supply pins or as close as possible to the MAX1214. Choose surface-mount capacitors, whose preferred location should be on the same side as the converter to save space and minimize the inductance. If close placement on the same side is not possible, these bypassing capacitors may be routed through vias to the bottom side of the PCB.

Multilayer boards with separated ground and power planes produce the highest level of signal integrity. Consider the use of a split ground plane arranged to match the physical location of analog and digital ground on the ADC's package. The two ground planes should be joined at a single point so the noisy digital ground currents do not interfere with the analog ground plane. The dynamic currents that may need to travel long distances before they are recombined at a common-source ground, resulting in large and undesirable ground loops, are a major concern with this approach. Ground loops can degrade the input noise by coupling back to the analog front-end of the converter, resulting in increased spurious activity, leading to decreased noise performance.

Alternatively, all ground pins could share the same ground plane, if the ground plane is sufficiently isolated from any noisy, digital systems ground. To minimize the coupling of the digital output signals from the analog input, segregate the digital output bus carefully from the analog input circuitry. To further minimize the effects of digital noise coupling, ground return vias can be positioned throughout the layout to divert digital switching currents away from the sensitive analog sections of the ADC. This approach does not require split ground planes, but can be accomplished by placing substantial ground connections between the analog front-end and the digital outputs.

The MAX1214 is packaged in a 68-pin QFN-EP package **(package code: G6800-4)**, providing greater design flexibility, increased thermal dissipation, and optimized AC performance of the ADC. The exposed paddle (EP) must be soldered down to AGND.

In this package, the data converter die is attached to an EP lead frame with the back of this frame exposed at the package bottom surface, facing the PCB side of the package. This allows a solid attachment of the package to the board with standard infrared (IR) flow soldering techniques.

Thermal efficiency is one of the factors for selecting a package with an exposed pad for the MAX1214. The exposed pad improves thermal and ensures a solid ground connection between the DAC and the PCB's analog ground layer.

Considerable care must be taken when routing the digital output traces for a high-speed, high-resolution data converter. It is recommended running the LVDS output traces as differential lines with 100Ω matched impedance from the ADC to the LVDS load device.

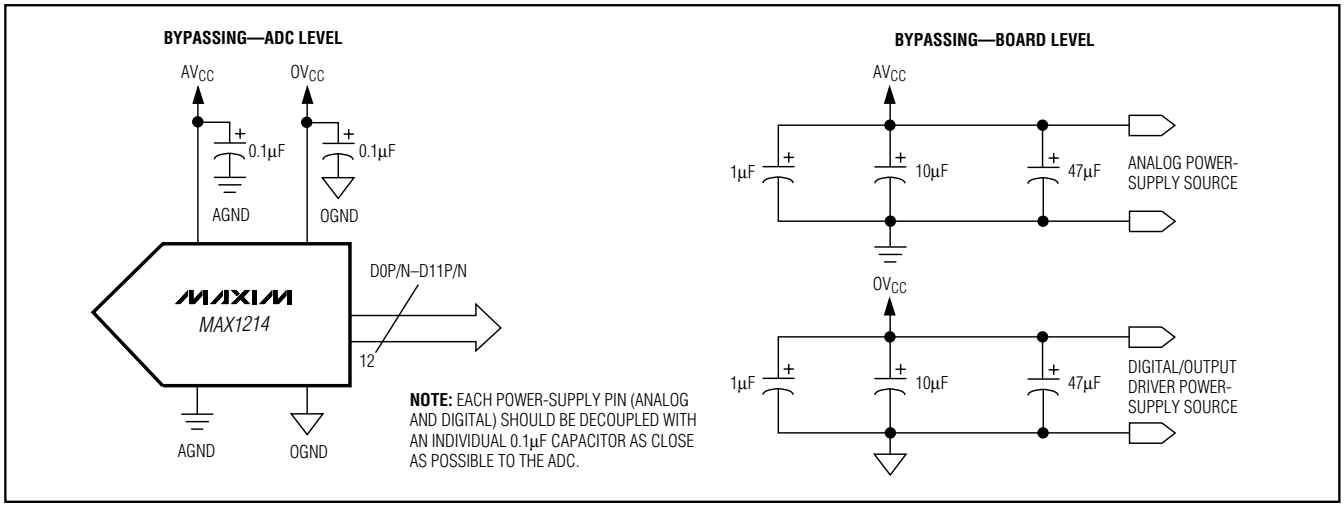

*Figure 10. Grounding, Bypassing, and Decoupling Recommendations for the MAX1214*

## Static Parameter Definitions

### Integral Nonlinearity (INL)

Integral nonlinearity is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best straight-line fit or a line drawn between the end points of the transfer function, once offset and gain errors have been nullified. However, the static linearity parameters for the MAX1214 are measured using the histogram method with a 10MHz input frequency.

### Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between an actual step width and the ideal value of 1LSB. A DNL error specification of less than 1LSB guarantees no missing codes and a monotonic transfer function. The MAX1214's DNL specification is measured with the histogram method based on a 10MHz input tone.

## Dynamic Parameter Definitions

### Aperture Jitter

Figure 11 depicts the aperture jitter ($t_{AJ}$), which is the sample-to-sample variation in the aperture delay.

### Aperture Delay

Aperture delay ($t_{AD}$) is the time defined between the rising edge of the sampling clock and the instant when an actual sample is taken (Figure 11).

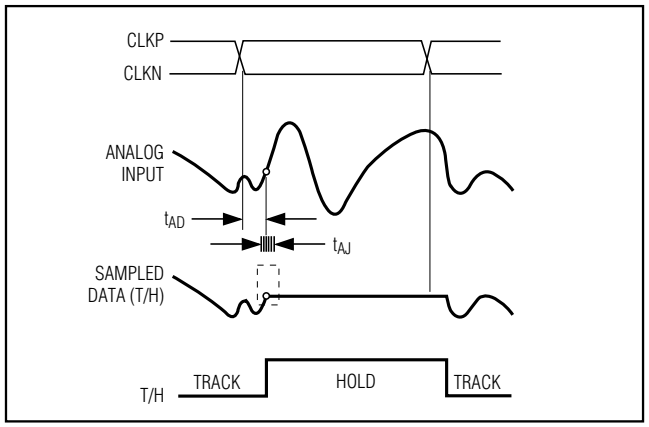

*Figure 11. Aperture Jitter/Delay Specifications*

### Signal-to-Noise Ratio (SNR)

For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization error only and results directly from the ADC's resolution (N bits):

$$SNR_{[max]} = 6.02 \times N + 1.76$$

In reality, other noise sources such as thermal noise, clock jitter, signal phase noise, and transfer function nonlinearities are also contributing to the SNR calculation and should be considered when determining the signal-to-noise ratio in ADC.

### Signal-to-Noise Plus Distortion (SINAD)

SINAD is computed by taking the ratio of the RMS signal to all spectral components excluding the fundamental and the DC offset. In the case of the MAX1214, SINAD is computed from a curve fit.

### Spurious-Free Dynamic Range (SFDR)

SFDR is the ratio of RMS amplitude of the carrier frequency (maximum signal component) to the RMS value of the next-largest noise or harmonic distortion component. SFDR is usually measured in dBc with respect to the carrier frequency amplitude or in dBFS with respect to the ADC's full-scale range.

### Intermodulation Distortion (IMD)

IMD is the ratio of the RMS sum of the intermodulation products to the RMS sum of the two fundamental input tones. This is expressed as:

$$IMD = 20 \times \log\left(\frac{\sqrt{V_{IM1}^2 + V_{IM2}^2 + ..... + V_{IM3}^2 + V_{IMn}^2}}{\sqrt{V_1^2 + V_2^2}}\right)$$

The fundamental input tone amplitudes ($V_1$ and $V_2$) are at -7dBFS. The intermodulation products are the amplitudes of the output spectrum at the following frequencies:

- Second-order intermodulation products: $f_{IN1} + f_{IN2}$, $f_{IN2} - f_{IN1}$
- Third-order intermodulation products: $2 \times f_{IN1} - f_{IN2}$, $2 \times f_{IN2} - f_{IN1}$, $2 \times f_{IN1} + f_{IN2}$, $2 \times f_{IN2} + f_{IN1}$
- Fourth-order intermodulation products: $3 \times f_{IN1} - f_{IN2}$, $3 \times f_{IN2} - f_{IN1}$, $3 \times f_{IN1} + f_{IN2}$, $3 \times f_{IN2} + f_{IN1}$
- Fifth-order intermodulation products: $3 \times f_{IN1} - 2 \times f_{IN2}$, $3 \times f_{IN2} - 2 \times f_{IN1}$, $3 \times f_{IN1} + 2 \times f_{IN2}$, $3 \times f_{IN2} + 2 \times f_{IN1}$

### Full-Power Bandwidth

A large -1dBFS analog input signal is applied to an ADC and the input frequency is swept up to the point where the amplitude of the digitized conversion result has decreased by 3dB. The -3dB point is defined as the full-power input bandwidth frequency of the ADC.

# 1.8V, 12-Bit, 210Msps ADC for Broadband Applications

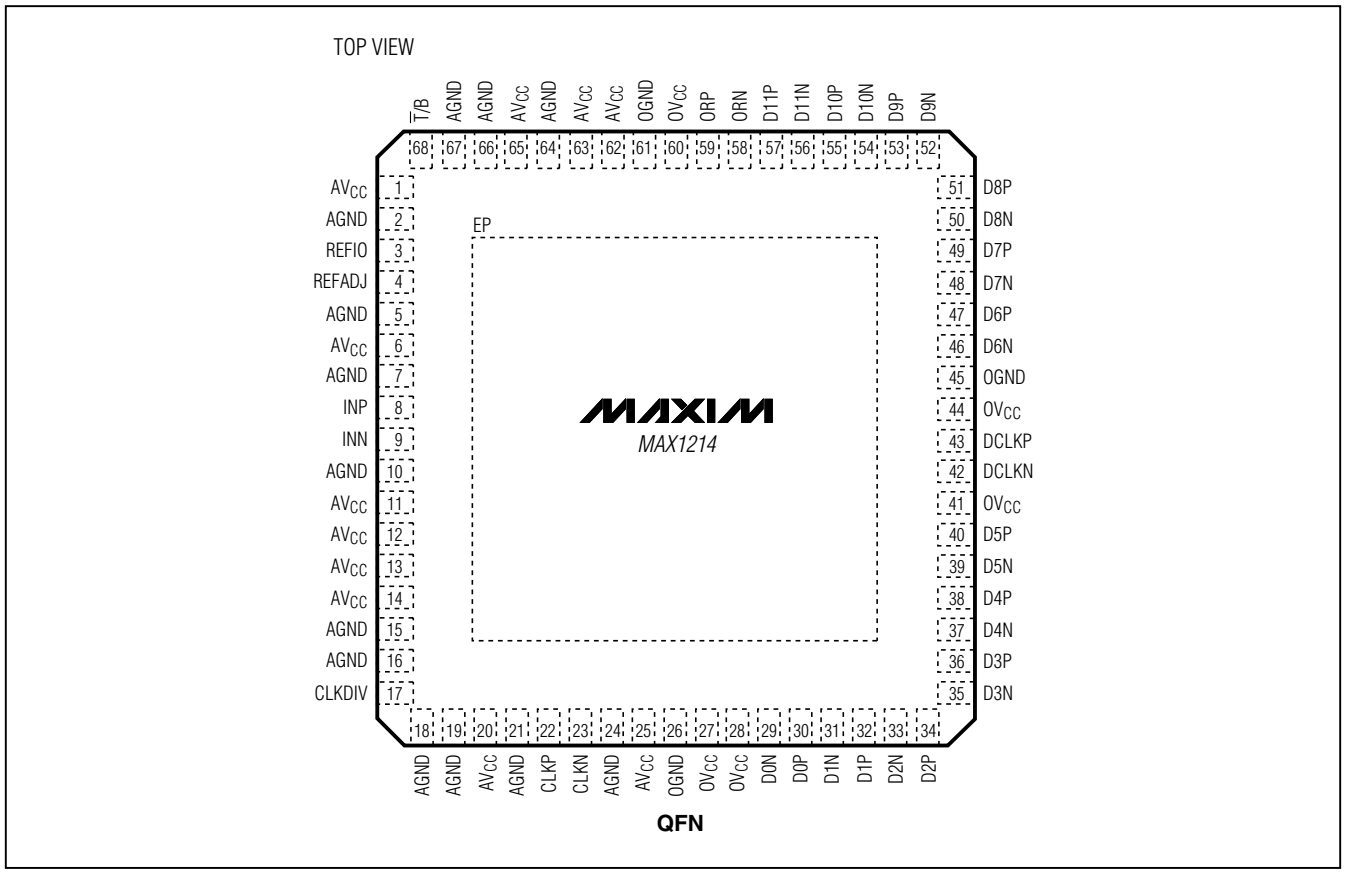

### Noise-Power Ratio (NPR)

NPR is commonly used to characterize the return path of cable systems where the signals are typically individual quadrature amplitude-modulated (QAM) carriers with a frequency spectrum similar to noise. Numerous such carriers are operated in a continuous spectrum, generating a noise-like signal, which covers a relatively broad bandwidth. To test the MAX1214 for NPR, a "noise-like" signal is passed through a high-order bandpass filter to produce an approximately square spectral pedestal of noise with about the same bandwidth as the signals being simulated. Following the bandpass filter, the signal is passed through a narrow band-reject filter to produce a deep notch at the center of the noise pedestal. Finally, this signal is applied to the MAX1214 and its digitized results analyzed. The RMS noise power of the signal inside the notch is compared with the RMS noise level outside the notch using an FFT. Note that the NPR test requires sufficiently long data records to guarantee a suitable number of samples inside the notch. NPR for the MAX1214 was determined for 50MHz noise bandwidth signals, simulating a typical cable signal environment (see the *Typical Operating Characteristics* for test details and results), and with a notch frequency of 28.8MHz.

## Pin-Compatible, Lower-Speed/Resolution Versions

Applications that require lower resolution, a choice of buffered or non-buffered outputs, and/or higher speed can refer to other family members of the MAX1214. Adjusting an application to a lower resolution has been simplified by maintaining an identical pinout for all members of this high-speed family. See the *Pin-Compatible Versions* table on the first page of this data sheet for a selection of different resolution and speed grades.
