DAC63204, DAC53204, DAC43204
SLASEX3A – MARCH 2021 – REVISED DECEMBER 2021

DACx3204 12-Bit, 10-Bit, and 8-Bit, Quad Voltage and Current Output Smart DACs With Auto-Detected I²C, PMBus™, or SPI Interface

1 Features

- Programmable voltage or current outputs with flexible configuration:
  - Voltage outputs:
    - 1 LSB INL and DNL (10-bit and 8-bit)
    - Gains of 1x, 1.5x, 2x, 3x, and 4x
  - Current outputs:
    - 1 LSB INL and DNL (8-bit)
    - ±25 µA, ±50 µA, ±125 µA, ±250 µA output range options
- Programmable comparator mode for all channels
- High-impedance output when VDD is off
- High-impedance and resistive pulldown power-down modes
- 50-MHz SPI-compatible interface
- Automatically detected I²C, PMBus™, or SPI interface
  - 1.62-V V_{IH} with V_{DD} = 5.5 V
- General-purpose input/output (GPIO) configurable as multiple functions
- Predefined waveform generation: sine wave, triangular, sawtooth
- User-programmable nonvolatile memory (NVM)
- Internal, external, or power-supply as reference
- Wide operating range:
  - Power supply: 1.8 V to 5.5 V
  - Temperature range: –40˚C to +125˚C
- Tiny package: 16-pin WQFN (3 mm × 3 mm)

2 Applications

- Rack server
- Optical module
- Inter-DC interconnect (metro)
- High performance computing
- Standard notebook PC

3 Description

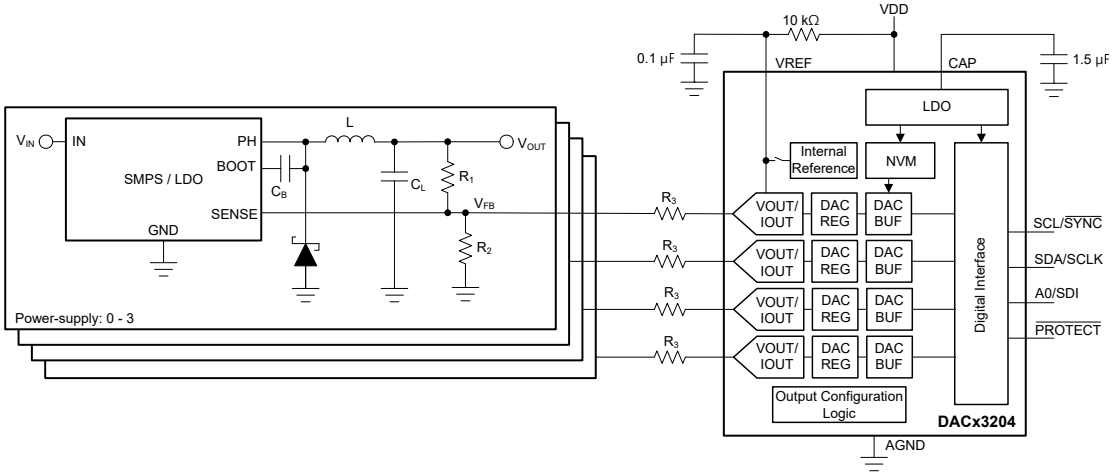

The 12-bit DAC63204, 10-bit DAC53204, and 8-bit DAC43204 (DACx3204) are a pin-compatible family of quad-channel, buffered, voltage-output and current-output smart digital-to-analog converters (DACs). These DACx3204 support Hi-Z power-down mode and Hi-Z output during power-off condition. The DAC outputs provide a force-sense option for use as a programmable comparator and current sink. The multifunction GPIO, function generation, and NVM enable these smart DACs for processor-less applications and design reuse. These devices automatically detect I²C, PMBus, and SPI interfaces and contain an internal reference.

The feature set combined with the tiny package and low power make these smart DACs an excellent choice for applications such as voltage margining and scaling, dc set-point for biasing and calibration, and waveform generation.

Device Information

PART NUMBER	PACKAGE(1)	BODY SIZE (NOM)
DACx3204	WQFN (16)	3.00 mm x 3.00 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

Voltage Margining and Scaling Using the DACx3204

An IMPORTANT NOTICE at the end of this data sheet addresses availability, warranty, changes, use in safety-critical applications, intellectual property matters and other important disclaimers. PRODUCTION DATA.

5 Pin Configuration and Functions

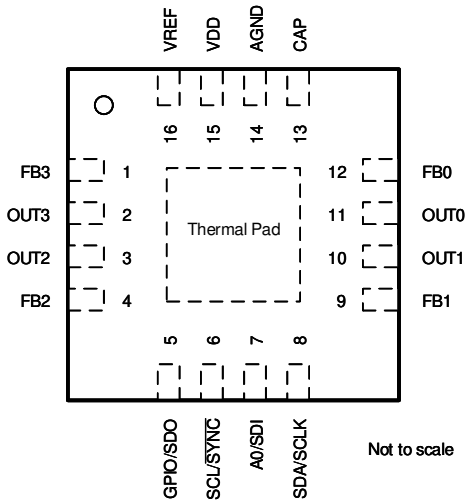

Figure 5-1. RTE Package, 16-pin WQFN, Top View

Table 5-1. Pin Functions

PIN		TYPE	DESCRIPTION
NO.	NAME		
1	FB3	Input	Voltage feedback pin for channel 3. In voltage-output mode, connect to OUT3 for closed-loop amplifier output. In current-output mode, keep the FB3 pin unconnected to minimize leakage current.
2	OUT3	Output	Analog output voltage from DAC channel 3.
3	OUT2	Output	Analog output voltage from DAC channel 2.
4	FB2	Input	Voltage feedback pin for channel 2. In voltage-output mode, connect to OUT2 for closed-loop amplifier output. In current-output mode, keep the FB2 pin unconnected to minimize leakage current.
5	GPIO/SDO	Input/Output	General-purpose input/output configurable as $\overline{\text{LDAC}}$, $\overline{\text{PD}}$, $\overline{\text{PROTECT}}$, $\overline{\text{RESET}}$, SDO, and $\overline{\text{STATUS}}$. For $\overline{\text{STATUS}}$ and SDO, connect the pin to the IO voltage with an external pullup resistor. If unused, connect the GPIO pin to VDD or AGND using an external resistor. This pin can ramp up before VDD.
6	SCL/$\overline{\text{SYNC}}$	Output	I^2C serial interface clock or SPI chip select input. This pin must be connected to the IO voltage using an external pullup resistor. This pin can ramp up before VDD.
7	A0/SDI	Input	Address configuration pin for I^2C or serial data input for SPI. For A0, connect this pin to VDD, AGND, SDA, or SCL for address configuration (Section 7.5.2.2.1). For SDI, this pin need not be pulled up or pulled down. This pin can ramp up before VDD.
8	SDA/SCLK	Input/Output	Bidirectional I^2C serial data bus or SPI clock input. This pin must be connected to the IO voltage using an external pullup resistor in the I^2C mode. This pin can ramp up before VDD.
9	FB1	Input	Voltage feedback pin for channel 1. In voltage-output mode, connect to OUT1 for closed-loop amplifier output. In current-output mode, keep the FB1 pin unconnected to minimize leakage current.
10	OUT1	Output	Analog output voltage from DAC channel 1.
11	OUT0	Output	Analog output voltage from DAC channel 0.
12	FB0	Input	Voltage feedback pin for channel 0. In voltage-output mode, connect to OUT0 for closed-loop amplifier output. In current-output mode, keep the FB0 pin unconnected to minimize leakage current.
13	CAP	Power	External bypass capacitor for the internal LDO. Connect a capacitor (approximately 1.5 µF) between CAP and AGND.
14	AGND	Ground	Ground reference point for all circuitry on the device.
15	VDD	Power	Supply voltage.
16	VREF	Power	External reference input. Connect a capacitor (approximately 0.1 µF) between VREF and AGND. Use a pullup resistor to VDD when the external reference is not used. This pin must not ramp up before VDD. In case an external reference is used, make sure the reference ramps up after VDD.
—	Thermal Pad	Ground	Connect the thermal pad to AGND.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

		MIN	MAX	UNIT
V_{DD}	Supply voltage, V_{DD} to A_{GND}	–0.3	6	V
	Digital inputs to A_{GND}	–0.3	V_{DD} + 0.3	V
	CAP to A_{GND}	–0.3	1.65	V
	V_{FBX} to A_{GND}	–0.3	V_{DD} + 0.3	V
	V_{OUTX} to A_{GND}	–0.3	V_{DD} + 0.3	V
V_{REF}	External reference, V_{REF} to A_{GND}	–0.3	V_{DD} + 0.3	V
	Current into any pin except the OUTx pins	–10	10	mA
T_J	Junction temperature	–40	150	°C
T_{stg}	Storage temperature	–65	150	°C

(1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins(1)	±2000	V
		Charged device model (CDM), per ANSI/ESDA/JEDEC JS-002, all pins(2)	±500	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V_{DD}	Positive supply voltage to ground (A_{GND})	1.7		5.5	V
V_{REF}	External reference to ground (A_{GND})	1.7		V_{DD}	V
V_{IH}	Digital input high voltage, 1.7 V < V_{DD} ≤ 5.5 V	1.62			V
V_{IL}	Digital input low voltage			0.4	V
C_{CAP}	External capacitor on CAP pin	0.5		15	µF
T_A	Ambient temperature	–40		125	°C

6.4 Thermal Information

THERMAL METRIC(1)		DACx3204 RTE (WQFN) 16 PINS	UNIT
$R_{θJA}$	Junction-to-ambient thermal resistance	49	°C/W
$R_{θJC(top)}$	Junction-to-case (top) thermal resistance	50	°C/W
$R_{θJB}$	Junction-to-board thermal resistance	24.1	°C/W
$Ψ_{JT}$	Junction-to-top characterization parameter	1.1	°C/W
$Ψ_{JB}$	Junction-to-board characterization parameter	24.1	°C/W
$R_{θJC(bot)}$	Junction-to-case (bottom) thermal resistance	8.7	°C/W

(1) For information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics application report.*

6.5 Electrical Characteristics: Voltage Output (continued)

all minimum/maximum specifications at T_A = –40°C to +125°C and typical specifications at T_A = 25°C, 1.7 V ≤ V_{DD} ≤ 5.5 V, DAC reference tied to VDD, gain = 1x, DAC output pin (OUT) loaded with resistive load (R_L = 5 kΩ to AGND) and capacitive load (C_L = 200 pF to AGND), and digital inputs at VDD or AGND (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
	Output-voltage headroom(2)	To V_{DD} (DAC output unloaded, internal reference = 1.21 V), V_{DD} ≥ 1.21 V × gain + 0.2 V	0.2			V
		To V_{DD} and A_{GND} (DAC output unloaded, external reference at V_{DD}, gain = 1x, the VREF pin is not shorted to VDD)	0.8			%FSR
		To V_{DD} and A_{GND} (I_{LOAD} = 10 mA at V_{DD} = 5.5 V, I_{LOAD} = 3 mA at V_{DD} = 2.7 V, I_{LOAD} = 1 mA at V_{DD} = 1.8 V), external reference at V_{DD}, gain = 1x, the VREF pin is not shorted to VDD	10			
Z_O	V_{FB} dc output impedance(3)	DAC output enabled, internal reference (gain = 1.5x or 2x) or external reference at V_{DD} (gain = 1x), the VREF pin is not shorted to VDD	400	500	600	kΩ
		DAC output enabled, internal V_{REF}, gain = 3x or 4x	325	400	485	
	Power supply rejection ratio (dc)	Internal V_{REF}, gain = 2x, DAC at midscale, V_{DD} = 5 V ±10%		0.25		mV/V
DYNAMIC PERFORMANCE						
t_{sett}	Output voltage settling time	1/4 to 3/4 scale and 3/4 to 1/4 scale settling to 10%FSR, V_{DD} = 5.5 V		20		µs
		1/4 to 3/4 scale and 3/4 to 1/4 scale settling to 10%FSR, V_{DD} = 5.5 V, internal V_{REF}, gain = 4x		25		
	Slew rate	V_{DD} = 5.5 V		0.3		V/µs
	Power-on glitch magnitude	At startup (DAC output disabled)		75		mV
		At startup (DAC output disabled), R_L = 100 kΩ		200		
	Output-enable glitch magnitude	DAC output disabled to enabled (DAC registers at zero scale), R_L = 100 kΩ		250		mV
V_n	Output noise voltage (peak to peak)	f = 0.1 Hz to 10 Hz, DAC at midscale, V_{DD} = 5.5 V		50		μV_{PP}
		Internal V_{REF}, gain = 4x, f = 0.1 Hz to 10 Hz, DAC at midscale, V_{DD} = 5.5 V		90		
	Output noise density	f = 1 kHz, DAC at midscale, V_{DD} = 5.5 V		0.35		$\mu V/\sqrt{Hz}$
		Internal V_{REF}, gain = 4x, f = 1 kHz, DAC at midscale, V_{DD} = 5.5 V		0.9		
	Power supply rejection ratio (ac)(3)	Internal V_{REF}, gain = 4x, 200-mV 50-Hz or 60-Hz sine wave superimposed on power supply voltage, DAC at midscale		-68		dB
	Code change glitch impulse	±1 LSB change around midscale (including feedthrough)		10		nV-s
	Code change glitch impulse magnitude	±1 LSB change around midscale (including feedthrough)		15		mV
POWER						
I_{DD}	Current flowing into VDD(4) (5)	Normal operation, DACs at full scale, digital pins static, external reference at V_{DD} but the VREF pin is not shorted to VDD		150		µA/ch

(1) Measured with DAC output unloaded. For external reference and internal reference V_{DD} ≥ 1.21 x gain + 0.2 V, between end-point codes: 32d to 4064d for 12-bit resolution, 8d to 1016d for 10-bit resolution, 2d to 254d for 8-bit resolution.
(2) Specified by design and characterization, not production tested.
(3) Specified with 200-mV headroom with respect to reference value when internal reference is used.
(4) Measured with DAC output unloaded.
(5) The total power consumption is calculated by I_{DD} x (total number of channels powered on) + (sleep-mode current).
(6) When a DAC channel is configured in IOUT mode for long term and then switched to VOUT mode, the VOUT mode can show parametric drift.

6.6 Electrical Characteristics: Current Output

all minimum/maximum specifications at T_A = –40°C to +125°C and typical specifications at T_A = 25°C, 1.7 V ≤ V_{DD} ≤ 5.5 V, ±250µA output range, and digital inputs at VDD or AGND (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
STATIC PERFORMANCE						
	Resolution		8			Bits
INL	Integral nonlinearity	DAC codes between 0d and 255d	–1		1	LSB
DNL	Differential nonlinearity	DAC codes between 0d and 255d	–1		1	LSB
	Offset error	DAC at midscale		±1		%FSR
	Gain error	DAC codes between 0d and 255d		±1.3		%FSR
OUTPUT						
	Output compliance voltage(1)	To V_{DD} and A_{GND}	400			mV
Z_O	I_{OUT} dc output impedance(2)	DAC at midscale, DAC output kept at V_{DD}/2	60			MΩ
	Power supply rejection ratio (dc)	DAC at midscale, all bipolar ranges, V_{DD} changed from 4.5V to 5.5V		0.23		LSB/V
DYNAMIC PERFORMANCE						
t_{sett}	Output current settling time	1/4 to 3/4 scale and 3/4 to 1/4 scale settling to 1 LSB at 8-bit resolution, V_{DD} = 5.5 V, common-mode voltage at OUTx pin is V_{DD}/2		60		µs
V_n	Output noise current (peak to peak)	0.1 Hz to 10 Hz, DAC at midscale, V_{DD} = 5.5 V, ±250-µA output range		150		nA_{PP}
	Output noise density	f = 1 kHz, DAC at midscale, V_{DD} = 5.5 V, ±250-µA output range		1		nA/√Hz
	Power supply rejection ratio (ac)(3)	±250 µA output range, 200-mV 50-Hz or 60-Hz sine wave superimposed on power-supply voltage, DAC at midscale		0.65		LSB/V
POWER						
I_{DD}	Current flowing into VDD(3) (4)	Normal operation, DACs at full scale, ±25-µA output range, digital pins static		42	50	µA/ch
		Normal operation, DACs at full scale, ±50-µA output range, digital pins static		56	70	
		Normal operation, DACs at full scale, ±125-µA output range, digital pins static		98	120	
		Normal operation, DACs at full scale, ±250-µA output range, digital pins static		167	200	

(1) Measured between DAC codes 0d and 255d.
(2) Specified by design and characterization, not production tested.
(3) The current flowing into V_{DD} does not account for the load current sourced or sinked on the OUTx pins. The VREF pin is connected to V_{DD}.
(4) The total power consumption is calculated by I_{DD} x (total number of channels powered on) + (sleep-mode current).

6.7 Electrical Characteristics: Comparator Mode

all minimum/maximum specifications at T_A = –40°C to +125°C and typical specifications at T_A = 25°C, 1.7 V ≤ V_{DD} ≤ 5.5 V, DAC reference tied to VDD, gain = 1x in voltage output mode, DAC output pin (OUT) loaded with resistive load (R_L = 5 kΩ to AGND) and capacitive load (C_L = 200 pF to AGND), and digital inputs at VDD or AGND (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
STATIC PERFORMANCE						
	Offset error(1) (2)	1.7 V ≤ V_{DD} ≤ 5.5 V, DAC at midscale, comparator input at Hi-Z, and DAC operating with external reference	–5	0	5	mV
	Offset error time drift(1)	V_{DD} = 5.5 V, external reference, T_A = 125°C, FBx in Hi-Z mode, DAC at full scale and V_{FB} at 0 V or DAC at zero scale and V_{FB} at 1.84 V, drift specified for 10 years of continuous operation		4		mV
OUTPUT						
	Input voltage	VREF connected to VDD, FBx resistor network connected to ground	0		V_{DD}	V
		VREF connected to VDD, FBx resistor network disconnected from ground	0		V_{DD} (1/3 – 1/100)	V
V_{OL}	Logic low output voltage	I_{LOAD} = 100 µA, output in open-drain mode		0.1		V
DYNAMIC PERFORMANCE						
t_{resp}	Output response time	DAC at midscale with 10-bit resolution, FBx input at Hi-Z, and transition step at FBx node is (V_{DAC} – 2 LSB) to (V_{DAC} + 2 LSB), transition time measured between 10% and 90% of output, output current of 100 µA, comparator output configured in push-pull mode, load capacitor at DAC output is 25 pF		10		µs

(1) Specified by design and characterization, not production tested.
(2) This specification does not include the total unadjusted error (TUE) of the DAC.

Copyright © 2021 Texas Instruments Incorporated

6.8 Electrical Characteristics: General

all minimum/maximum specifications at T_A = –40°C to +125°C and typical specifications at T_A = 25°C, 1.7 V ≤ V_{DD} ≤ 5.5 V, DAC reference tied to VDD, gain = 1x in voltage output mode or ±250µA output range in current output mode, DAC output pin (OUT) loaded with resistive load (R_L = 5 kΩ to AGND) in voltage-output mode and capacitive load (C_L = 200 pF to AGND), and digital inputs at VDD or AGND (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
INTERNAL REFERENCE						
	Initial accuracy	T_A = 25°C	1.1979	1.212	1.224	V
	Reference output temperature coefficient(1) (2)				50	ppm/°C
EXTERNAL REFERENCE						
	V_{REF} input impedance(1) (3)			192		kΩ/ch
EEPROM						
	Endurance(1)	–40°C ≤ T_A ≤ +85°C		20000		Cycles
		T_A = 125°C		1000		
	Data retention(1)	T_A = 25°C		50		Years
	EEPROM programming write cycle time(1)				200	ms
	Device boot-up time(1)	Time taken from power valid (V_{DD} ≥ 1.7 V) to output valid state (output state as programmed in EEPROM), 0.5-µF capacitor on the CAP pin		5		ms
DIGITAL INPUTS						
	Digital feedthrough	Voltage output mode, DAC output static at midscale, fast mode plus, SCL toggling		20		nV-s
	Pin capacitance	Per pin		10		pF
POWER-DOWN MODE						
I_{DD}	Current flowing into VDD(1)	DAC in sleep mode, internal reference powered down, external reference at 5.5 V			28	µA
		DAC in sleep mode, internal reference enabled, additional current through internal reference		10		
		DAC channels enabled, internal reference enabled, additional current through internal reference per DAC channel in voltage-output mode		12.5		
HIGH-IMPEDANCE OUTPUT						
I_{LEAK}	Current flowing into V_{OUTX} and V_{FBX}	DAC in Hi-Z output mode, 1.7 V ≤ V_{DD} ≤ 5.5 V		10		nA
		V_{DD} = 0 V, V_{OUT} ≤ 1.5 V, decoupling capacitor between V_{DD} and AGND = 0.1 µF		200		
		V_{DD} = 0 V, 1.5 V < V_{OUT} ≤ 5.5 V, decoupling capacitor between V_{DD} and AGND = 0.1 µF		500		
		100 kΩ between V_{DD} and AGND, V_{OUT} ≤ 1.25 V, series resistance of 10 kΩ at OUTx pin		±2		µA

(1) Specified by design and characterization, not production tested.
(2) Measured at –40°C and +125°C and calculated the slope.
(3) Impedances for the DAC channels are connected in parallel.

6.15 Timing Requirements: GPIO

all input signals are specified with $t_r = t_f$ = 1 V/ns (10% to 90% of V_{IO}) and timed from a voltage level of (VIL + VIH) / 2, 1.7 V ≤ V_{IO} ≤ 5.5 V, 1.7 V ≤ V_{DD} ≤ 5.5 V, and –40°C ≤ T_A ≤ +125°C

		MIN	NOM	MAX	UNIT
$t_{GPIHIGH}$	GPI high time(1)	2			µs
t_{GPILOW}	GPI low time(1)	2			µs
t_{GPAWGD}	$\overline{LDAC}$ falling edge to DAC update delay(2)			2	µs
$t_{CS2LDAC}$	$\overline{SYNC}$ rising edge to $\overline{LDAC}$ falling edge	1			µs
$t_{STP2LDAC}$	I^2C stop bit rising edge to $\overline{LDAC}$ falling edge	1			µs
t_{LDACW}	$\overline{LDAC}$ low time	2			µs

(1) The SCL, SDA, A0, and A1 pins can be configured as GPIOs that perform different channel-specific or independent operations. The actual response time of the GPIO is determined by the delay provided by the configured function and the settling time of the DAC.
(2) The GPIOs can be configured as channel-specific or global $\overline{LDAC}$ function.

7 Detailed Description

7.1 Overview

The 12-bit DAC63204,10-bit DAC53204, and 8-bit DAC43204 (DACx3204) are a pin-compatible family of quad-channel buffered voltage-output and current-output, smart digital-to-analog converters (DACs). The DAC channels are independently configurable as voltage or current output. The DAC outputs change to Hi-Z when VDD is off; a feature useful in voltage-margining applications. These smart DACs contain nonvolatile memory (NVM), an internal reference, automatically detectable I^2C and SPI interface, PMBus-compatibility in I^2C mode, force-sense output, and a general-purpose input. These devices support Hi-Z power-down modes by default, which can be configured to 10 kΩ-GND or 100 kΩ-GND using the NVM. The DACx3204 have a power-on-reset (POR) circuit that makes sure all the registers start with default or user-programmed settings using NVM. The DACx3204 operate with either an internal reference, external reference, or with a power supply as the reference, and provide a full-scale output of 1.8 V to 5.5 V.

The DACx3204 devices support I^2C standard mode (100 kbps), fast mode (400 kbps), and fast mode plus (1 Mbps). The I^2C interface can be configured with four target addresses using the A0 pin. These devices also support specific PMBus commands such as *turn on/off*, *margin high or low*, and more. The SPI mode supports a 3-wire interface by default with up to 50-MHz SCLK input. The GPIO input can be configured as SDO in the NVM for SPI read capability. The GPIO input can alternatively be configurable as $\overline{\text{LDAC}}$, $\overline{\text{PD}}$, $\overline{\text{STATUS}}$, $\overline{\text{FAULT-DUMP}}$, $\overline{\text{RESET}}$,and $\overline{\text{PROTECT}}$ functions.

The DACx3204 also include digital slew rate control, and support standard waveform generation such as *sine and cosine*, *triangular*, and *sawtooth* waveforms. These devices can generate pulse-width modulation (PWM) output with the combination of the triangular or sawtooth waveform and the FB pin. The force-sense outputs of the DAC channels can be used as programmable comparators. The comparator mode allows programmable hysteresis, latching comparator, window comparator, and fault-dump to the NVM. These features enable the DACx3204 to go beyond the limitations of a conventional DAC that depends on a processor to function. As a result of processor-less operation and the *smart* feature set, the DACx3204 are called smart DACs.

7.2 Functional Block Diagram

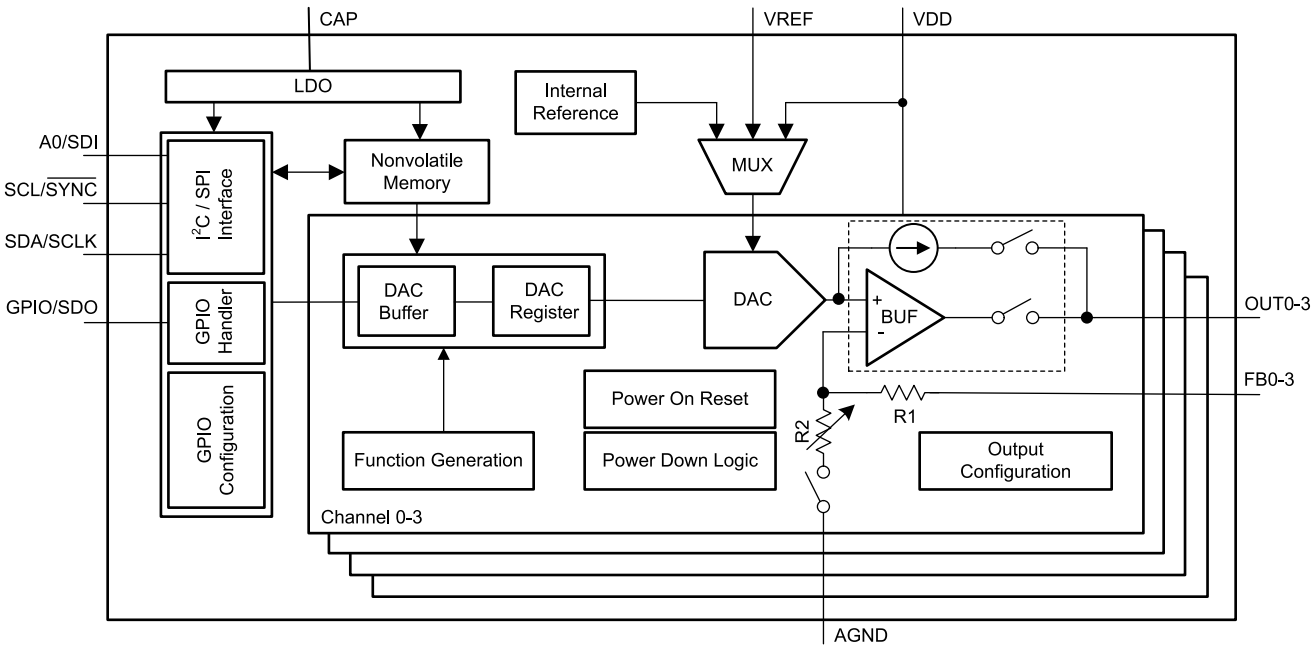

Figure 7-1. Functional Block Diagram

7.3 Feature Description

7.3.1 Smart Digital-to-Analog Converter (DAC) Architecture

The DACx3204 devices consist of string architecture with a voltage-output amplifier and an external FB pin and voltage-to-current converter for each channel. Section 7.2 shows the DAC architecture within the block diagram, which operates from a 1.8-V to 5.5-V power supply. The DAC has an internal voltage reference of 1.21 V. There is an option to select an external reference on the VREF pin or the power supply as a reference. The voltage output mode uses one of these three reference options. The current output mode uses an internal band gap to generate the current outputs. Both the voltage- and current-output modes support multiple programmable output ranges.

The DACx3204 devices support Hi-Z output when VDD is off, maintaining very low leakage current at the output pins with up to 1.25 V of forced voltage. The DAC output pin also starts up in high-impedance mode by default, making these devices an excellent choice for voltage margining and scaling applications. To change the power-up mode to 10 kΩ-GND or 100 kΩ-GND, program the corresponding VOUT-PDN-X field in the COMMON-CONFIG register and load these bits in the device NVM.

The DACx3204 devices support an independent comparator mode for each channel. The respective FBx pins act as the inputs for the comparator. The DAC architecture supports inversion of the comparator output using register settings. The comparator outputs can be push-pull or open-drain. The comparator mode supports programmable hysteresis using *margin-high* and *margin-low* register fields, latching comparator, and window comparator. The comparator outputs are accessible internally by the device.

The DACx3204 devices include a *smart* feature set to enable processor-less operation and high-integration. The NVM enables a predictable start-up. The GPIO triggers the DAC output without the I^2C interface in the absence of a processor or when the processor or software fails. The integrated functions and the FBx pin enable PWM output for control applications. The FBx pin enables this device to be used as a programmable comparator. The digital slew-rate control and the Hi-Z power-down modes enable a hassle-free voltage margining and scaling function.

7.3.2 Digital Input/Output

The DACx3204 have four digital IO pins that include I^2C, SPI, PMBus, and GPIO interfaces. These devices automatically detect I^2C and SPI protocols at the first successful communication after power-on, and then connect to the detected interface. After an interface protocol is connected, any change in the protocol is ignored. The I^2C interface uses the A0 pin to select from among four address options. The SPI interface is a 3-wire interface by default. No readback capability is available in this mode. The GPIO pin can be configured in the register map and then programmed in to the NVM as the SDO pin. The SPI readback mode is slower than the write mode. The programming interface pins are:

- I^2C: SCL, SDA, A0
- SPI: SCLK, SDI, $\overline{\text{SYNC}}$, SDO/GPIO

The GPIO can be configured as multiple functions other than SDO. These are $\overline{\text{LDAC}}$, $\overline{\text{PD}}$, $\overline{\text{STATUS}}$, $\overline{\text{PROTECT}}$, $\overline{\text{FAULT-DUMP}}$, and $\overline{\text{RESET}}$. All the digital pins are open-drain when used as outputs. Therefore, all the output pins must be pulled up to the desired IO voltage using external resistors.

Copyright © 2021 Texas Instruments Incorporated

7.3.3 Nonvolatile Memory (NVM)

The DACx3204 contain nonvolatile memory (NVM) bits. These memory bits are user programmable and erasable, and retain the set values in the absence of a power supply. All the register bits, as shown in the highlighted gray cells in Table 7-20, can be stored in the NVM by setting NVM-PROG = 1 in the COMMON-TRIGGER register. The NVM-PROG is an autoresetting bit. The default values for all the registers in the DACx3204 are loaded from NVM as soon as a POR event is issued.

The DACx3204 also implement NVM-RELOAD bit in the COMMON-TRIGGER register. Set this bit to 1 for the device to start an NVM-reload operation. After completion, the device autoresets the NVM-RELOAD bit to 0. During the NVM write or reload operation, all read/write operations to the device are blocked. Section 6.8 provides the timing specification for the NVM write cycle. The processor must wait for the specified duration before resuming any read or write operation on the SPI or I^2C interface.

Copyright © 2021 Texas Instruments Incorporated

7.4 Device Functional Modes

7.4.1 Voltage-Output Mode

The voltage-output mode for each DAC channel can be entered by selecting the power-up option in the VOUT-PDN-X fields in the COMMON-CONFIG register and simultaneously powering down the current output option for the respective channels using the IOUT-PDN-X bits in the same register. Short the OUTx and FBx pins of respective channels externally for closed-loop amplifier output. An open FBx pin saturates the amplifier output. To achieve the desired voltage output, select the correct reference option, select the amplifier gain for the required output range, and program the DAC code in the DAC-X-DATA register of the respective channels.

7.4.1.1 Voltage Reference and DAC Transfer Function

There are three voltage reference options possible with the DACx3204: internal reference, external reference, and the power supply as reference, as shown in Figure 7-2. The DAC transfer function in the voltage-output and comparator modes changes based on the voltage reference selection.

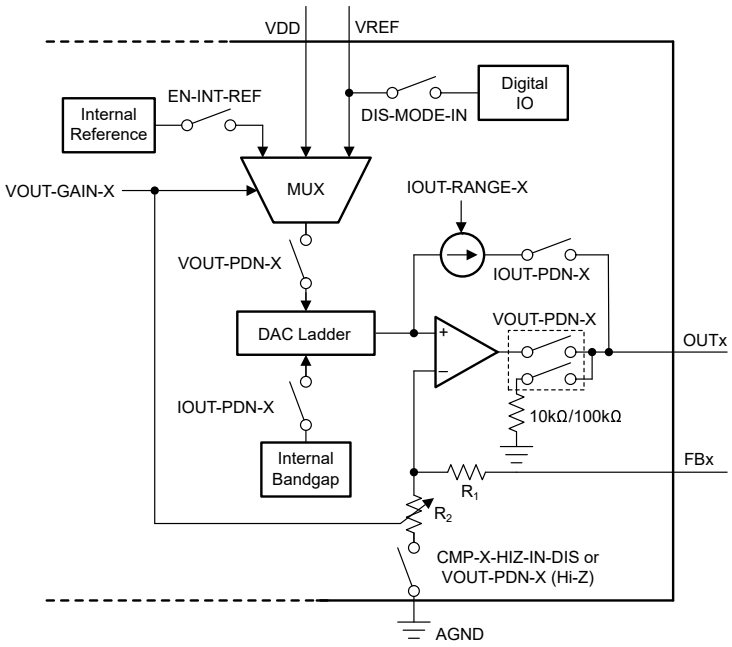

Figure 7-2. Voltage Reference Selection and Power-Down Logic

7.4.1.1.1 Internal Reference

The DACx3204 contain an internal reference that is disabled by default. To enable the internal reference, write 1 to bit EN-INT-REF in the COMMON-CONFIG register. The internal reference generates a fixed 1.21-V voltage (typical). Use the VOUT-GAIN-X bit in the DAC-X-VOUT-CMP-CONFIG register to achieve gains of 1.5x, 2x, 3x, or 4x for the DAC output voltage (V_{OUT}). Equation 1 shows DAC transfer function using the internal reference.

$$V_{OUT} = \frac{DAC_DATA}{2^N} \times V_{REF} \times GAIN \quad (1)$$

where:

- N is the resolution in bits, 8 (DAC43204), 10 (DAC53204), or 12 (DAC63204).
- DAC_DATA is the decimal equivalent of the binary code that is loaded to the DAC-X-DATA bit in the DAC-X-DATA register. DAC_DATA ranges from 0 to $2^N - 1$.
- V_{REF} is the internal reference voltage = 1.21 V (typical).
- GAIN = 1.5x, 2x, 3x, or 4x, based on VOUT-X-GAIN bits.

Copyright © 2021 Texas Instruments Incorporated

7.4.1.1.2 External Reference

By default, the DACx3204 operate from an external reference input. The external reference option can also be selected by configuring the VOUT-GAIN-X field in the DAC-X-VOUT-CMP-CONFIG register appropriately. Write 1 to the DIS-MODE-IN bit in the DEVICE-MODE-CONFIG register to minimize I_{DD}. The external reference can be between 1.7 V and VDD. Equation 2 shows DAC transfer function when the external reference is used. The gain at the output stage of the DAC is always 1x in the external reference mode.

Note

The external reference must be less than VDD in both transient and steady-state conditions. Therefore, the external reference must ramp up after VDD and ramp down before VDD.

$$V_{OUT} = \frac{DAC_DATA}{2^N} \times V_{REF} \quad (2)$$

where:

- N is the resolution in bits, 8 (DAC43204), 10 (DAC53204), or 12 (DAC63204).
- DAC_DATA is the decimal equivalent of the binary code that is loaded to the DAC-X-DATA field in the DAC-X-DATA register. DAC_DATA ranges from 0 to $2^N – 1$.
- V_{REF} is the external reference voltage.

7.4.1.1.3 Power-Supply as Reference

The DACx3204 can operate with the power-supply pin (VDD) as a reference. Equation 3 shows DAC transfer function when the power-supply pin is used as reference. The gain at the output stage is always 1x.

$$V_{OUT} = \frac{DAC_DATA}{2^N} \times V_{DD} \quad (3)$$

where:

- N is the resolution in bits, either 8 (DAC43204), 10 (DAC53204), or 12 (DAC63204).
- DAC_DATA is the decimal equivalent of the binary code that is loaded to the DAC-X-DATA bit in the DAC-X-DATA register.
- DAC_DATA ranges from 0 to $2^N – 1$.
- V_{DD} is used as the DAC reference voltage.

7.4.2 Current-Output Mode

To enter current-output mode for each DAC channel, disable the respective IOUT-PDN-X bits in the COMMON-CONFIG register, and set the respective VOUT-PDN-X bits in the same register to Hi-Z power-down mode. Select the desired current-output range by writing to the IOUT-RANGE-X bit in the DAC-X-IOUT-MISC-CONFIG register. To minimize leakage in current-output mode, disconnect the FBx pin. For the best power-on glitch performance, program the NVM with IOUT mode using the smallest output range before powering on the output channel, and then immediately program the DAC code and desired output range. The transfer function of the output current is shown in Equation 4.

$$I_{OUT} = \frac{DAC_DATA \times (I_{MAX} - I_{MIN})}{2^8} + I_{MIN} \quad (4)$$

where:

- DAC_DATA is the decimal equivalent of the binary code that is loaded to the DAC-X-DATA bit as specified in Section 7.6.8 for all variants or Section 7.6.19 for DAC43204. DAC_DATA ranges from 0 to 255.
- I_{MAX} is the signed maximum current in the IOUT-RANGE-X setting as specified in Section 7.6.5.
- I_{MIN} is the signed minimum current in the IOUT-RANGE-X setting as specified in Section 7.6.5.

Copyright © 2021 Texas Instruments Incorporated

7.4.3 Comparator Mode

All the DAC channels can be configured as programmable comparators in the voltage-output mode. To enter the comparator mode for a channel, write 1 to the CMP-X-EN bit in the respective DAC-X-VOUT-CMP-CONFIG register. The comparator output can be configured as push-pull or open-drain using the CMP-X-OD-EN bit. To enable the comparator output on the output pin, write 1 to the CMP-X-OUT-EN bit. To invert the comparator output, write 1 to the CMP-X-INV-EN bit. The FBx pin has a finite impedance. By default, the FBx pin is in the high-impedance mode. To disable high-impedance on the FBx pin, write 1 to the CMP-X-HIZ-IN-DIS bit. Table 7-1 shows the comparator output at the pin for different bit settings.

Note

In the Hi-Z input mode, the comparator input range is limited to:

- For GAIN = 1x, 1.5x, or 2x: $V_{FB} \leq (V_{REF} \times GAIN) / 3$
- For GAIN = 3x, or 4x: $V_{FB} \leq (V_{REF} \times GAIN) / 6$

Any higher input voltage is clipped.

Table 7-1. Comparator Output Configuration

CMP-X-EN	CMP-X-OUT-EN	CMP-X-OD-EN	CMP-X-INV-EN	CMPX-OUT PIN
0	X	X	X	Comparator not enabled
1	0	X	X	No output
1	1	0	0	Push-pull output
1	1	0	1	Push-pull and inverted output
1	1	1	0	Open-drain output
1	1	1	1	Open-drain and inverted output

Figure 7-3 shows the interface circuit when all the DAC channels are configured as comparators. The programmable comparator operation is as shown in Figure 7-4. Individual comparator channels can be configured in no-hysteresis, with-hysteresis, and window-comparator modes using the CMP-X-MODE bit in the respective DAC-X-CMP-MODE-CONFIG register, as shown in Table 7-2.

7.4.3.1 Programmable Hysteresis Comparator

Comparator mode provides hysteresis when the CMP-X-MODE bit is set to 01b, as shown in Table 7-2. The hysteresis is provided by the DAC-X-MARGIN-HIGH and DAC-X-MARGIN-LOW registers, as shown in Figure 7-5.

When the DAC-X-MARGIN-HIGH is set to full-code or the DAC-X-MARGIN-LOW is set to zero-code, the comparator works as a latching comparator that is, the output is latched after the threshold is crossed. The latched output can be reset by writing to the corresponding RST-CMP-FLAG-X bit in the COMMON-DAC-TRIG register. Figure 7-6 shows the behavior of a latching comparator with active low output and Figure 7-7 shows the behavior of a latching comparator with active high output.

Note

The value of the DAC-X-MARGIN-HIGH register must be greater than the value of the DAC-X-MARGIN-LOW register. The comparator output in the hysteresis mode can only be noninverting that is, the CMP-X-INV-EN bit in the DAC-X-VOUT-CMP-CONFIG register must be set to 0. In latching mode, for the reset to take effect, the input voltage must be within DAC-X-MARGIN-HIGH and DAC-X-MARGIN-LOW.

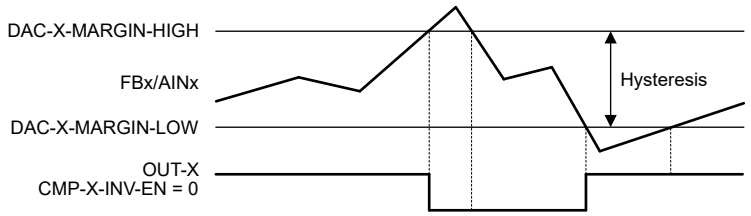

Figure 7-5. Programmable Hysteresis Without Latching Output

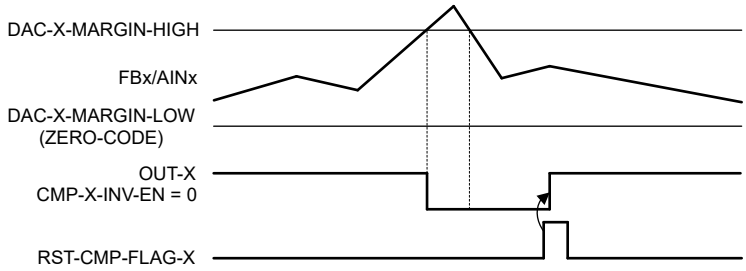

Figure 7-6. Latching Comparator With Active Low Output

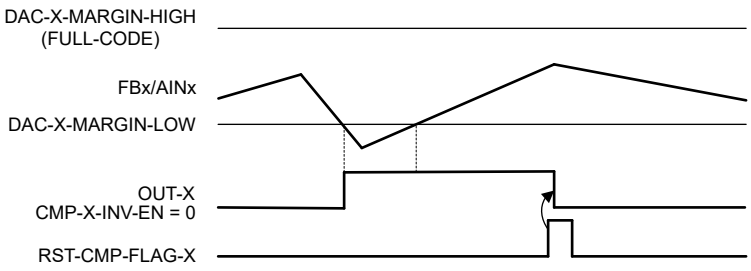

Figure 7-7. Latching Comparator With Active High Output

Copyright © 2021 Texas Instruments Incorporated

7.4.3.2 Programmable Window Comparator

Window comparator mode is enabled by setting the CMP-X-MODE bit to 10b, as shown in Table 7-2. The window bounds are set by the DAC-X-MARGIN-HIGH and the DAC-X-MARGIN-LOW registers, as shown in Figure 7-8. The output of the window comparator for a given channel is indicated by the respective WIN-CMP-X bit in the CMP-STATUS register. The comparator output (WIN-CMP-X) can be latched by writing 1 to the WIN-LATCH-EN bit in the COMMON-CONFIG register. After being latched, the comparator output can be reset using the corresponding RST-CMP-FLAG-X bit in the COMMON-DAC-TRIG register. For the reset to take effect, the input must be within the window bounds.

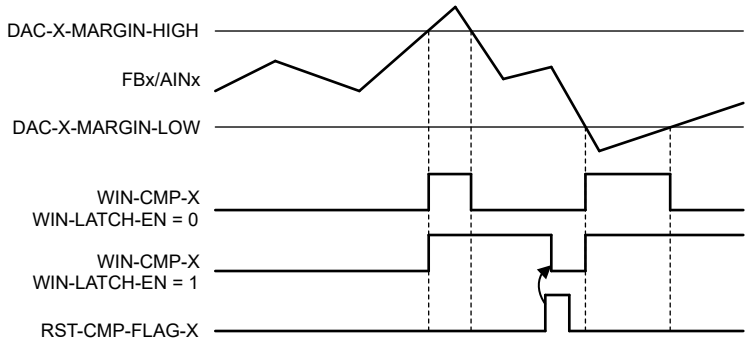

Figure 7-8. Window Comparator Operation

A single comparator is used per channel to check both the *margin-high* and *margin-low* limits of the window. Therefore, the window comparator function has a finite response time as specified in Section 6.7. Also, the static behavior of the WIN-CMP-X bit is not reflected at the output pins. Set the CMP-X-OUT-EN bit to 0. The WIN-CMP-X bit must be read digitally using the communication interface. This bit can also be mapped to the GPIO pin, as shown in Table 7-19.

Note

- The value of the DAC-X-MARGIN-HIGH register must be greater than that of the DAC-X-MARGIN-LOW register.
- Set the SLEW-RATE-X bit to 0000b (no-slew) and LOG-SLEW-EN-X bit to 0b in the DAC-X-FUNC-CONFIG register to get the best response time from the window comparator.
- The CMP-X-OUT-EN bit in the DAC-X-VOUT-CMP-CONFIG register can be set to 0b to eliminate undesired toggling of the OUT pin.

7.4.4 Fault-Dump Mode

The DACx3204 provides a feature to save a few registers into the NVM when the FAULT-DUMP bit is triggered or the GPIO mapped to fault-dump (as shown in Table 7-18) is triggered. This feature is useful in system-level fault management to capture the state of the device or system just before a fault is triggered, to allow diagnosis after the fault has occurred. The registers saved when fault-dump is triggered, are:

- CMP-STATUS[7:0]
- DAC-0-DATA[15:8]
- DAC-1-DATA[15:8]
- DAC-2-DATA[15:8]
- DAC-3-DATA[15:8]

Note

When the fault-dump cycle is in progress, any change in the data can corrupt the final outcome. Make sure the comparator and the DAC codes are stable during the NVM write cycle.

Table 7-3 shows the storage format of the registers in the NVM.

Copyright © 2021 Texas Instruments Incorporated

Table 7-3. Fault-Dump NVM Storage Format

NVM ROWS	B31-B24	B23-B16	B15-B8	B7-B0
Row1	CMP-STATUS[7:0]	Don't care		
Row2	DAC-0-DATA[15:8]	DAC-1-DATA[15:8]	DAC-2-DATA[15:8]	DAC-3-DATA[15:8]

The data captured in the NVM after the fault dump can be read in a specific sequence:

1. Set the EE-READ-ADDR bit to 0b in the COMMON-CONFIG register, to select row1 of the NVM.
2. Trigger the read of the selected NVM row by writing 1 to the READ-ONE-TRIG in the COMMON-TRIGGER register; this bit autoresets. This action copies that data from the selected NVM row to SRAM addresses 0x9D (LSB 16 bits from the NVM) and 0x9E (MSB 16 bits from the NVM).
3. To read the SRAM data:
   a. Write 0x009D to the SRAM-CONFIG register.
   b. Read the data from the SRAM-DATA register to get the LSB 16 bits.
   c. Write 0x009E to the SRAM-CONFIG register.
   d. Read the data from the SRAM-DATA register again to get the MSB bits.
4. Set the EE-READ-ADDR bit to 1b in the COMMON-CONFIG register, to select row2 of the NVM. Repeat steps 2 and 3.

7.4.5 Application-Specific Modes

This section provides the details of application-specific functional modes available in DACx3204.

7.4.5.1 Voltage Margining and Scaling

Voltage margining or scaling is a primary application for DACx3204. This section provides specific features available for this application such as Hi-Z output, slew-rate control, $\overline{\text{PROTECT}}$ input, and PMBus compatibility.

7.4.5.1.1 High-Impedance Output and $\overline{\text{PROTECT}}$ Input

All the DAC output channels remain in high-impedance (Hi-Z) when VDD is off. Figure 7-9 shows a simplified schematic of DACx3204 used in a voltage-margining application. The series resistor R_S is needed in voltage-output mode, but is optional in current-output mode. Almost all linear regulators and DC/DC converters have a feedback voltage of ≤ 1.25 V. The low-leakage currents at the outputs are maintained for V_{FB} of ≤ 1.25 V. Thus, for all practical purposes, the DAC outputs appear as Hi-Z when VDD of the DAC is off in voltage margining and scaling applications. This feature allows for seamless integration of the DACx3204 into a system without any need for additional power-supply sequencing for the DAC.

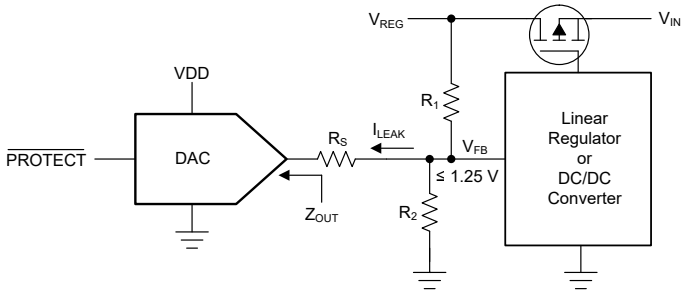

Figure 7-9. High-Impedance (Hi-Z) Output and $\overline{\text{PROTECT}}$ Input

The DAC channels power down to Hi-Z at boot up. The outputs can power up with a preprogrammed code that corresponds to the nominal output of the DC/DC converter or the linear regulator. This feature allows for smooth power up and power down of the DAC without impacting the feedback loop of the DC/DC converter or the linear regulator.

The GPIO pin of the DACx3204 can be configured as a $\overline{\text{PROTECT}}$ function, as shown in Table 7-18. $\overline{\text{PROTECT}}$ takes the DAC outputs to a predictable state with a slewed or direct transition. This function is useful in systems where a fault condition (such as a brownout), a subsystem failure, or a software crash requires that the DAC outputs reach a predefined state without the involvement of a processor. The detected event can be fed to the GPIO pin that is configured as the $\overline{\text{PROTECT}}$ input. The $\overline{\text{PROTECT}}$ function can also be triggered using

Copyright © 2021 Texas Instruments Incorporated

the PROTECT bit in the COMMON-TRIGGER register. Configure the behavior of the $\overline{\text{PROTECT}}$ function in the PROTECT-CONFIG field in the DEVICE-MODE-CONFIG register, as shown in Table 7-4.

Note

- After the $\overline{\text{PROTECT}}$ function is triggered, the write functionality is disabled on the communication interface until the function is completed.
- The PROTECT-FLAG bit in the CMP-STATUS register is set to 1 when the $\overline{\text{PROTECT}}$ function is triggered. This bit can be polled by reading the CMP-STATUS register. After the $\overline{\text{PROTECT}}$ function is complete, a read command on the CMP-STATUS register resets the PROTECT-FLAG bit.

Table 7-4. $\overline{\text{PROTECT}}$ Function Configuration

PROTECT-CONFIG FIELD	FUNCTION
00	Switch to Hi-Z power-down (no slew).
01	Switch to DAC code stored in NVM (no slew) and then switch to Hi-Z power-down.
10	Slew to margin-low code and then switch to Hi-Z power-down.
11	Slew to margin-high code and then switch to Hi-Z power-down.

7.4.5.1.2 Programmable Slew-Rate Control

When the DAC data registers are written, the voltage on DAC output (V_{OUT}) immediately transitions to the new code following the slew rate and settling time specified in the *Electrical Characteristics*.

The slew rate control feature allows the user to control the rate at which the output voltage (V_{OUT}) changes. When this feature is enabled (using the SLEW-RATE-X[3:0] bits), the DAC output changes from the current code to the code in the DAC-X-MARGIN-HIGH or DAC-X-MARGIN-LOW registers (when margin high or low commands are issued to the DAC) using the step size and time-period per step set in CODE-STEP-X and SLEW-RATE-X bits in the DAC-X-FUNC-CONFIG register:

- SLEW-RATE-X defines the time-period per step at which the digital slew updates.
- CODE-STEP-X defines the number of LSBs by which the output value changes at each update, for the corresponding channels.

Table 7-5 and Table 7-6 show different settings available for CODE-STEP-X and SLEW-RATE-X. With the default slew rate control setting of no-slew, the output changes immediately at a rate limited by the output drive circuitry and the attached load.

When the slew rate control feature is used, the output changes happen at the programmed slew rate. This configuration results in a staircase formation at the output as shown in Figure 7-10. Do not write to CODE-STEP-X, SLEW-RATE-X, or DAC-X-DATA during the output slew operation. Equation 5 provides the equation for the calculating the slew time (t_{SLEW}).

7.4.5.1.3 PMBus Compatibility Mode

The PMBus protocol is an I²C-based communication standard for power-supply management. PMBus contains standard command codes tailored to power supply applications. The DACx3204 implement some PMBus commands such as *Turn Off*, *Turn On*, *Margin Low*, *Margin High*, *Communication Failure Alert Bit (CML)*, as well as *PMBUS revision*. Figure 7-11 shows typical PMBus connections. The EN-PMBUS bit in the INTERFACE-CONFIG register must be set to 1 to enable the PMBus protocol.

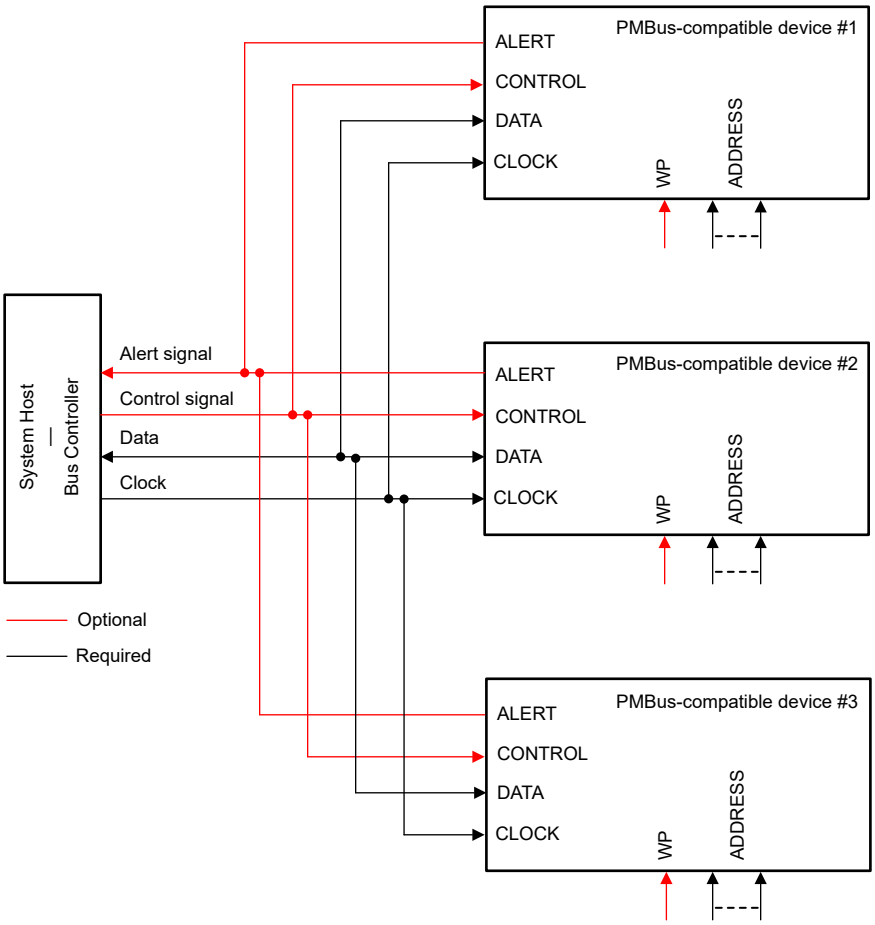

Figure 7-11. PMBus Connections

Similar to I²C, PMBus is a variable length packet of 8-bit data bytes, each with a receiver acknowledge, wrapped between a start and stop bit. The first byte is always a 7-bit *target address* followed by a *write* bit, sometimes called the *even address* that identifies the intended receiver of the packet. The second byte is an 8-bit *command* byte, identifying the PMBus command being transmitted using the respective command code. After the command byte, the transmitter either sends data associated with the command to write to the receiver command register (from least significant byte to most significant byte, as shown in Table 7-7), or sends a new start bit indicating the desire to read the data associated with the command register from the receiver. Then the receiver transmits the data following the same least significant byte first format (see Table 7-8).

Table 7-7. PMBus Update Sequence

MSB	....	LSB	ACK	MSB	...	LSB	ACK	MSB	...	LSB	ACK	MSB	...	LSB	ACK
Address (A) byte Section 7.5.2.2.1				Command byte Section 7.5.2.2.2				Data byte - LSDB				Data byte - MSDB (Optional)

From Controller				Target	From Controller			Target	From Controller				Target	From Target			Controller	From Target			Controller

The DACx3204 I²C interface implements some of the PMBus commands. Table 7-9 shows the supported PMBus commands that are implemented in DACx3204.The DAC uses DAC-X-MARGIN-LOW, DAC-X-MARGIN-HIGH bits, SLEW-RATE-X, and CODE-STEP-X bits for PMBUS-OPERATION-CMD-X. To access multiple channels, write the PMBus page address as specified in Table 7-21 to the PMBUS-PAGE register first, followed by a write to the channel-specific register.

Table 7-9. PMBus Operation Commands

REGISTER	PMBUS-OPERATION-CMD-X[15:8]	DESCRIPTION
PMBUS-OP-CMD-X	00h	Turn off
	80h	Turn on
	94h	Margin low
	A4h	Margin high

The DACx3204 also implement PMBus features such as group command protocol and communication time-out failure. The CML bit in the PMBUS-CML register indicates a communication fault in the PMBus. This bit is reset by writing 1.

To get the PMBus version, read the PMBUS-VERSION register.

Copyright © 2021 Texas Instruments Incorporated

7.4.5.2 Function Generation

The DACx3204 implement a continuous function or waveform generation feature. These devices can generate a triangular wave, sawtooth wave, and sine wave independently for every channel.

7.4.5.2.1 Triangular Waveform Generation

The triangular waveform uses the DAC-X-MARGIN-LOW and DAC-X-MARGIN-HIGH registers for minimum and maximum levels, respectively. The frequency of the waveform depends on the min and max levels, CODE-STEP and SLEW-RATE settings as shown in Equation 6. An external RC load with a time-constant larger than the slew-rate settings can be dominant over the internal frequency calculation. The CODE-STEP-X and SLEW-RATE-X settings are available in the DAC-X-FUNC-CONFIG register. Writing 0b000 to the FUNC-CONFIG-X bit field in the DAC-X-FUNC-CONFIG register selects triangular waveform.

$$f_{TRIANGLE_WAVE} = \frac{1}{2 \times SLEW_RATE \times \left(\frac{MARGIN_HIGH - MARGIN_LOW + 1}{CODE_STEP}\right)} \quad (6)$$

where:

- SLEW_RATE is the SLEW-RATE-X setting as specified in Table 7-6.
- CODE_STEP is the CODE-STEP-X setting as specified in Table 7-5.
- MARGIN_HIGH is the DAC-X-MAGIN-HIGH as specified in Section 7.6.2.
- MARGIN_LOW is the DAC-X-MAGIN-LOW as specified in Section 7.6.3.

7.4.5.2.2 Sawtooth Waveform Generation

The sawtooth and the inverse sawtooth waveforms use the DAC-X-MARGIN-LOW and DAC-X-MARGIN-HIGH registers for minimum and maximum levels, respectively. The frequency of the waveform depends on the min and max levels, CODE-STEP and SLEW-RATE settings as shown in Equation 7. An external RC load with a time constant larger than the slew-rate settings can be dominant over the internal frequency calculation. The CODE-STEP-X and SLEW-RATE-X settings are available in the DAC-X-FUNC-CONFIG register. Write 0b001 to the FUNC-CONFIG-X bit field in the DAC-X-FUNC-CONFIG register to select sawtooth waveform, and write 0b010 to select inverse sawtooth waveform.

$$f_{SAWTOOTH_WAVE} = \frac{1}{SLEW_RATE \times \left(\frac{MARGIN_HIGH - MARGIN_LOW + 1}{CODE_STEP}\right)} \quad (7)$$

where:

- SLEW_RATE is the SLEW-RATE-X setting as specified in Table 7-6.
- CODE_STEP is the CODE-STEP-X setting as specified in Table 7-5.
- MARGIN_HIGH is the DAC-X-MAGIN-HIGH as specified in Section 7.6.2.
- MARGIN_LOW is the DAC-X-MAGIN-LOW as specified in Section 7.6.3.

Copyright © 2021 Texas Instruments Incorporated

7.4.5.2.3 Sine Waveform Generation

The sine wave function uses 24 preprogrammed points per cycle. The frequency of the sine wave depends on the SLEW-RATE settings as shown in Equation 8:

$$f_{SINE_WAVE} = \frac{1}{24 \times SLEW_RATE} \quad (8)$$

where SLEW_RATE is the SLEW-RATE-X setting as specified in Table 7-6.

An external RC load with a time constant larger than the slew-rate settings can be dominant over the internal frequency calculation. The SLEW-RATE-X setting is available in the DAC-X-FUNC-CONFIG register. Writing 0b100 to the FUNC-CONFIG-X bit field in the DAC-X-FUNC-CONFIG register selects sine wave. The codes for the sine wave are fixed. Use the gain settings at the output amplifier for changing the full-scale output using the internal reference option. The gain settings are accessible through the VOUT-GAIN-X bits in the DAC-X-VOUT-CMP-CONFIG register. Table 7-10 shows the list of hard-coded discrete points for the sine wave with 12-bit resolution and Figure 7-12 shows the pictorial representation of the sine wave. There are four phase settings available for the sine wave that are selected using the PHASE-SEL-X bit in the DAC-X-FUNC-CONFIG register.

Table 7-10. Sine Wave Data Points

SEQUENCE	12-BIT VALUE	SEQUENCE	12-BIT VALUE
0	0x800	12	0x800
1	0x9A8	13	0x658
2	0xB33	14	0x4CD

7.4.6 Device Reset and Fault Management

This section provides the details of power-on-reset (POR), software reset, and other diagnostics and fault-management features of DACx3204.

7.4.6.1 Power-On Reset (POR)

The DACx3204 family of devices includes a power-on reset (POR) function that controls the output voltage at power up. After the V_{DD} supply has been established, a POR event is issued. The POR causes all registers to initialize to default values, and communication with the device is valid only after a POR (boot-up) delay. The default value for all the registers in the DACx3204 is loaded from NVM as soon as the POR event is issued.

When the device powers up, a POR circuit sets the device to the default mode. The POR circuit requires specific V_{DD} levels, as indicated in Figure 7-13, to make sure that the internal capacitors discharge and reset the device at power up. To make sure that a POR occurs, V_{DD} must be less than 0.7 V for at least 1 ms. When V_{DD} drops to less than 1.65 V, but remains greater than 0.7 V (shown as the undefined region), the device may or may not reset under all specified temperature and power-supply conditions. In this case, initiate a POR. When V_{DD} remains greater than 1.65 V, a POR does not occur.

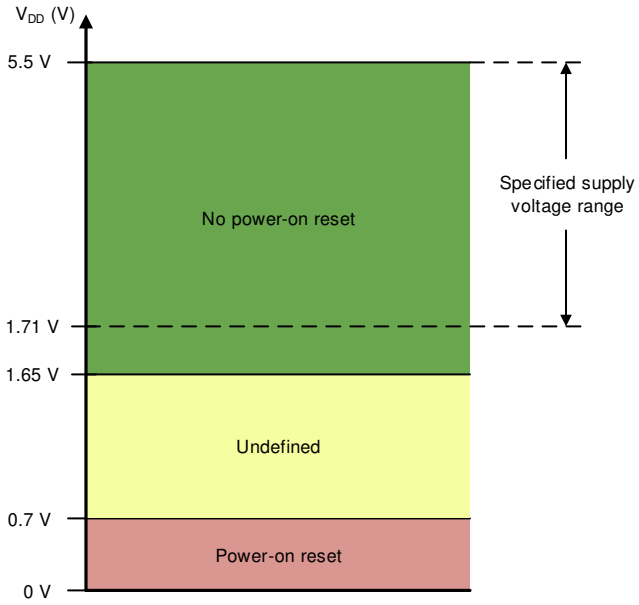

Figure 7-13. Threshold Levels for V_{DD} POR Circuit

7.4.6.2 External Reset

An external reset to the device can be triggered through the GPIO pin or through the register map. To initiate a device software reset event, write the reserved code 1010 to the RESET field in the COMMON-TRIGGER register. A software reset initiates a POR event. The GPIO pin can be configured as a $\overline{\text{RESET}}$ pin as shown in Table 7-18. This configuration must be programmed into the NVM so that the setting is not cleared after the device reset. The $\overline{\text{RESET}}$ input must be a low pulse. The device starts the boot-up sequence after the falling edge of the $\overline{\text{RESET}}$ input. The rising edge of the $\overline{\text{RESET}}$ input does not have any effect.

7.4.6.3 Register-Map Lock

The DACx3204 implement a register-map lock feature that prevents an accidental or unintended write to the DAC registers. The device locks all the registers when the DEV-LOCK bit in the COMMON-CONFIG register is set to 1. However, the software reset function through the COMMON-TRIGGER register is not blocked when using I^2C interface. To bypass the DEV-LOCK setting, write 0101 to the DEV-UNLOCK bits in the COMMON-TRIGGER register.

Copyright © 2021 Texas Instruments Incorporated

7.4.6.4 NVM Cyclic Redundancy Check (CRC)

The DACx3204 implement a cyclic redundancy check (CRC) feature for the NVM to make sure that the data stored in the NVM is uncorrupted. There are two types of CRC alarm bits implemented in DACx3204:

- NVM-CRC-FAIL-USER
- NVM-CRC-FAIL-INT

The NVM-CRC-FAIL-USER bit indicates the status of user-programmable NVM bits, and the NVM-CRC-FAIL-INT bit indicates the status of internal NVM bits The CRC feature is implemented by storing a 16-Bit CRC (CRC-16-CCITT) along with the NVM data each time NVM program operation (write or reload) is performed and during the device start up. The device reads the NVM data and validates the data with the stored CRC. The CRC alarm bits (NVM-CRC-FAIL-USER and NVM-CRC-FAIL-INT in the GENERAL-STATUS register) report any errors after the data are read from the device NVM. The alarm bits are set only at boot-up.

7.4.6.4.1 NVM-CRC-FAIL-USER Bit

A logic 1 on NVM-CRC-FAIL-USER bit indicates that the user-programmable NVM data are corrupt. During this condition, all registers in the DAC are initialized with factory reset values, and any DAC registers can be written to or read from. To reset the alarm bits to 0, issue a software reset (see *Section 7.4.6.2*) command, or cycle power to the DAC. A software reset or power-cycle also reloads the user-programmable NVM bits. In case the failure persists, reprogram the NVM.

7.4.6.4.2 NVM-CRC-FAIL-INT Bit

A logic 1 on NVM-CRC-FAIL-INT bit indicates that the internal NVM data are corrupt. During this condition, all registers in the DAC are initialized with factory reset values, and any DAC registers can be written to or read from. In case of a temporary failure, to reset the alarm bits to 0, issue a software reset (see *Section 7.4.6.2*) command or cycle power to the DAC. A permanent failure in the NVM makes the device unusable.

Copyright © 2021 Texas Instruments Incorporated

7.4.7 Power-Down Mode

The DACx3204 output amplifier and internal reference can be independently powered down through the EN-INT-REF, VOUT-PDN-X, and IOUT-PDN-X bits in the COMMON-CONFIG register, as shown in Figure 7-2. At power up, the DAC output and the internal reference are disabled by default. In power-down mode, the DAC outputs (OUTx pins) are in a high-impedance state. To change this state to 10 kΩ-A_{GND} or 100 kΩ-A_{GND} in the voltage-output mode (at power up), use the VOUT-PDN-X bits. The power-down state for current-output mode is always high-impedance.

The DAC power-up state can be programmed to any state (power-down or normal mode) using the NVM. Table 7-11 shows the DAC power-down bits. The individual channel power-down bits or the global device power-down function can be mapped to the GPIO pin using the GPIO-CONFIG register.

Table 7-11. DAC Power-Down Bits

REGISTER	VOUT-PDN-X[1]	VOUT-PDN-X[0]	IOUT-PDN-X	DESCRIPTION
COMMON-CONFIG	0	0	1	Power up VOUT-X.
	0	1	1	Power down VOUT-X with 10 kΩ to AGND. Power down IOUT-X to Hi-Z.
	1	0	1	Power down VOUT-X with 100 kΩ to AGND. Power down IOUT-X to Hi-Z.
	1	1	1	Power down VOUT-X to Hi-Z. Power down IOUT-X to Hi-Z (default).
	1	1	0	Power down VOUT-X to Hi-Z. Power up IOUT-X.

7.5 Programming

The DACx3204 are programmed through either a 3-wire SPI or 2-wire I^2C interface. A 4-wire SPI mode is enabled by mapping the GPIO pin as SDO. The SPI readback operates at a lower SCLK than the standard SPI write operation. The type of interface is determined based on the first protocol to communicate after device power up. After the interface type is determined, the device ignores any change in the type while the device is on. The interface type can be changed after a power cycle.

7.5.1 SPI Programming Mode

An SPI access cycle for DACx3204 is initiated by asserting the $\overline{\text{SYNC}}$ pin low. The serial clock, SCLK, can be a continuous or gated clock. SDI data are clocked on SCLK falling edges. The SPI frame for DACx3204 is 24 bits long. Therefore, the $\overline{\text{SYNC}}$ pin must stay low for at least 24 SCLK falling edges. The access cycle ends when the $\overline{\text{SYNC}}$ pin is deasserted high. If the access cycle contains less than the minimum clock edges, the communication is ignored. By default, the SDO pin is not enabled (three-wire SPI). In the three-wire SPI mode, if the access cycle contains more than the minimum clock edges, only the first 24 bits are used by the device. When $\overline{\text{SYNC}}$ is high, the SCLK and SDI signals are blocked, and SDO becomes Hi-Z to allow data readback from other devices connected on the bus.

Table 7-12 and Figure 7-14 describe the format for the 24-bit SPI access cycle. The first byte input to SDI is the instruction cycle. The instruction cycle identifies the request as a read or write command and the 7-bit address that is to be accessed. The last 16 bits in the cycle form the data cycle.

Table 7-12. SPI Read/Write Access Cycle

BIT	FIELD	DESCRIPTION
23	R/$\overline{\text{W}}$	Identifies the communication as a read or write command to the address register: R/$\overline{\text{W}}$ = 0 sets a write operation. R/$\overline{\text{W}}$ = 1 sets a read operation
22-16	A[6:0]	Register address: specifies the register to be accessed during the read or write operation
15-0	DI[15:0]	Data cycle bits: If a write command, the data cycle bits are the values to be written to the register with address A[6:0]. If a read command, the data cycle bits are *don't care* values.

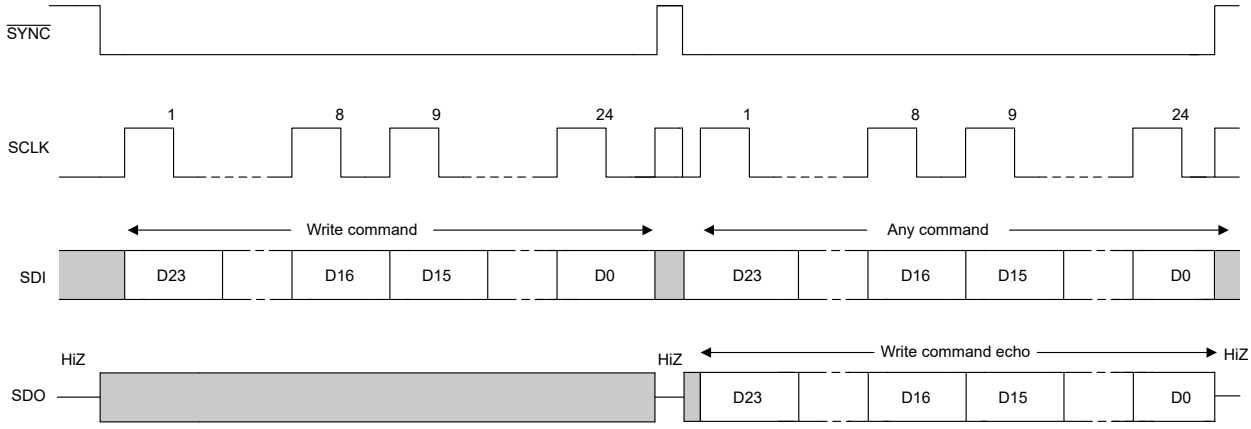

Figure 7-14. SPI Write Cycle

Read operations require that the SDO pin is first enabled by setting the SDO-EN bit in the INTERFACE-CONFIG register. This configuration is called four-wire SPI. A read operation is initiated by issuing a read command access cycle. After the read command, a second access cycle must be issued to get the requested data. The output data format is shown in Table 7-13 and Figure 7-15. Data are clocked out on the SDO pin either on the falling edge or rising edge of SCLK according to the FSDO bit, as shown in Figure 6-3.

Table 7-13. SDO Output Access Cycle

BIT	FIELD	DESCRIPTION
23	R/$\overline{\text{W}}$	Echo R/$\overline{\text{W}}$ from previous access cycle
22-16	A[6:0]	Echo register address from previous access cycle
15-0	DI[15:0]	Readback data requested on previous access cycle

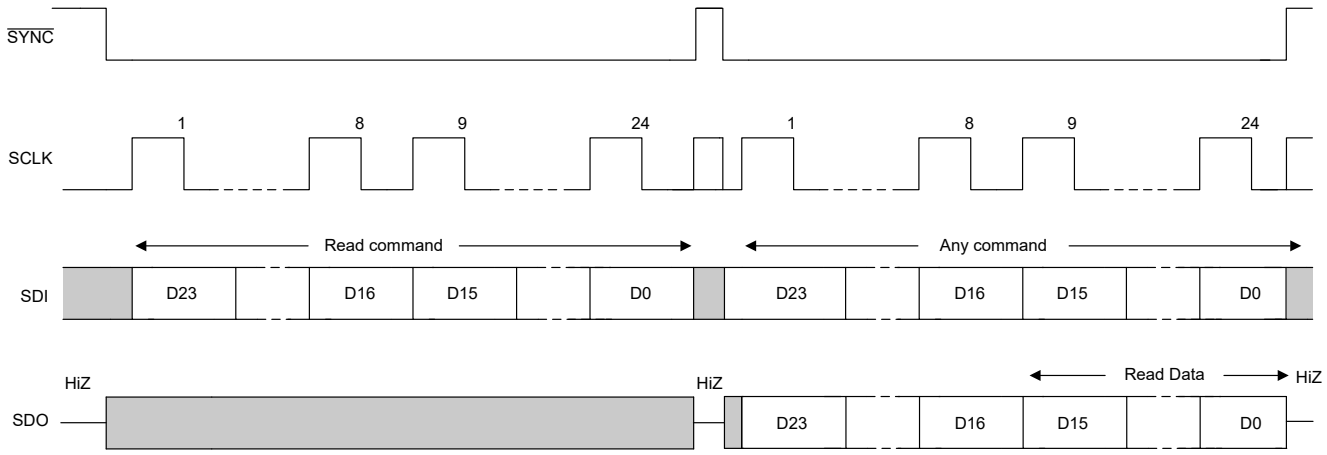

Figure 7-15. SPI Read Cycle

The daisy-chain operation is also enabled with the SDO pin. In daisy-chain mode, multiple devices are connected in a *chain* with the SDO pin of one device is connected to SDI pin of the following device, as shown in Figure 7-16. The SPI host drives the SDI pin of the first device in the chain. The SDO pin of the last device in the chain is connected to the POCI pin of the SPI host. In four-wire SPI mode, if the access cycle contains multiples of 24 clock edges, only the last 24 bits are used by the device first device in the chain. If the access cycle contains clock edges that are not in multiples of 24, the SPI packet is ignored by the device. Figure 7-17 describes the packet format for the daisy-chain write cycle.

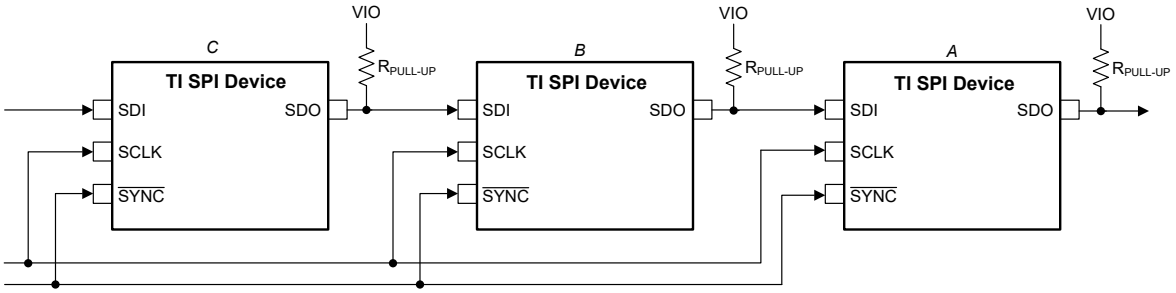

Figure 7-16. SPI Daisy-Chain Connection

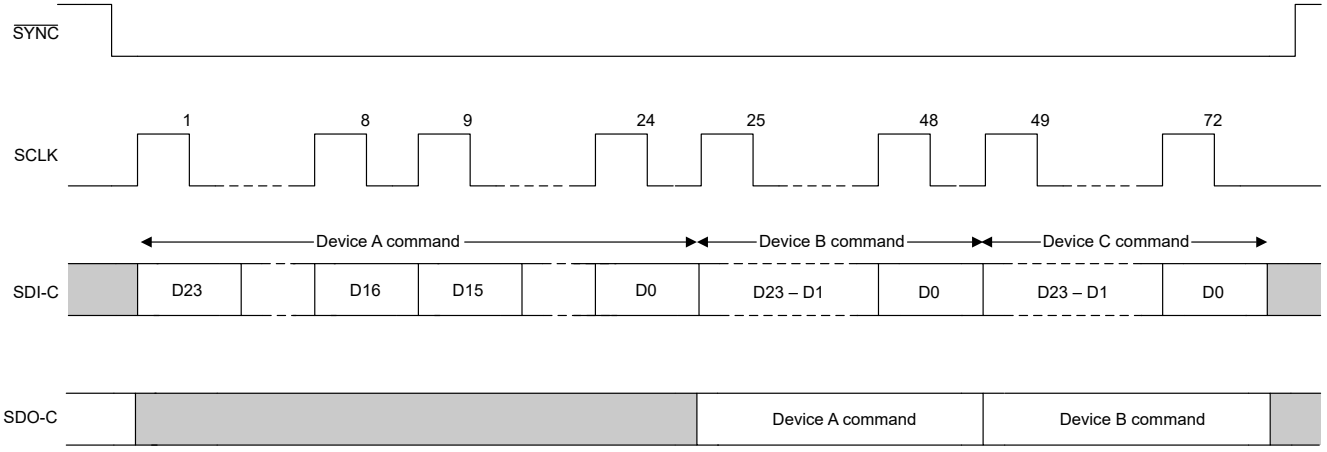

Figure 7-17. SPI Daisy-Chain Write Cycle

7.5.2 I²C Programming Mode

The DACx3204 devices have a 2-wire serial interface (SCL and SDA), and one address pin (A0), as shown in the pin diagram, Figure 5-1. The I²C bus consists of a data line (SDA) and a clock line (SCL) with pullup structures. When the bus is idle, both SDA and SCL lines are pulled high. All the I²C-compatible devices connect to the I²C bus through the open drain I/O pins, SDA and SCL.

The I²C specification states that the device that controls communication is called a *controller*, and the devices that are controlled by the controller are called *targets*. The controller generates the SCL signal. The controller also generates special timing conditions (start condition, repeated start condition, and stop condition) on the bus to indicate the start or stop of a data transfer. Device addressing is completed by the controller. The controller on an I²C bus is typically a microcontroller or digital signal processor (DSP). The DACx3204 family operates as a target on the I²C bus. A target acknowledges controller commands, and upon controller control, receives or transmits data.

Typically, the DACx3204 family operates as a target receiver. A controller writes to the DACx3204, a target receiver. However, if a controller requires the DACx3204 internal register data, the DACx3204 operate as a target transmitter. In this case, the controller reads from the DACx3204. According to I²C terminology, read and write refer to the controller.

The DACx3204 family supports the following data transfer modes:

- Standard mode (100 kbps)
- Fast mode (400 kbps)
- Fast mode plus (1.0 Mbps)

The data transfer protocol for standard and fast modes is exactly the same; therefore, both modes are referred to as *F/S-mode* in this document. The fast mode plus protocol is supported in terms of data transfer speed, but not output current. The low-level output current would be 3 mA; similar to the case of standard and fast modes. The DACx3204 family supports 7-bit addressing. The 10-bit addressing mode is not supported. The device supports the general call reset function. Sending the following sequence initiates a software reset within the device: start or repeated start, 0x00, 0x06, stop. The reset is asserted within the device on the rising edge of the ACK bit, following the second byte.

Other than specific timing signals, the I²C interface works with serial bytes. At the end of each byte, a ninth clock cycle generates and detects an acknowledge signal. An acknowledge is when the SDA line is pulled low during the high period of the ninth clock cycle. A not-acknowledge is when the SDA line is left high during the high period of the ninth clock cycle, as shown in Figure 7-18.

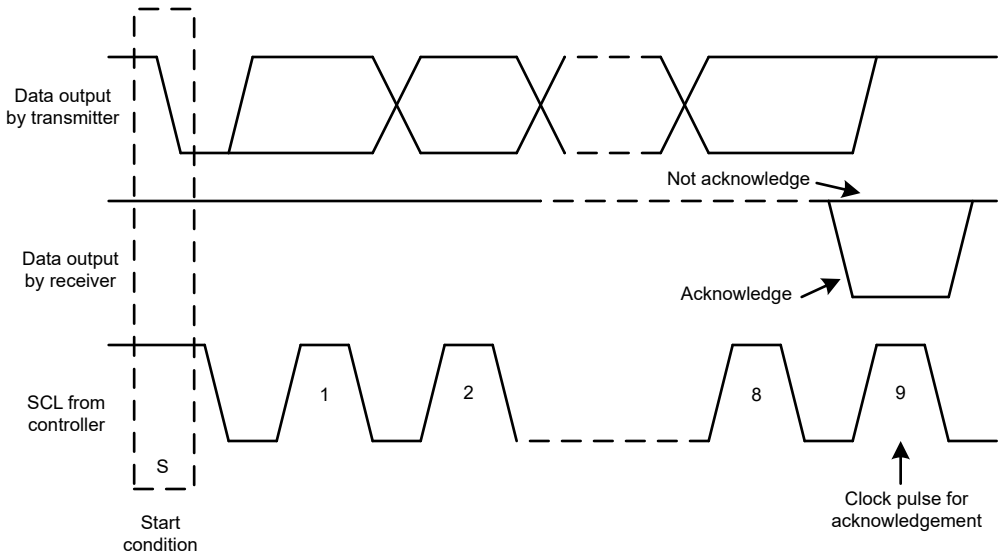

Figure 7-18. Acknowledge and Not Acknowledge on the I²C Bus

7.5.2.1 F/S Mode Protocol

The following steps explain a complete transaction in F/S mode.

1. The controller initiates data transfer by generating a start condition. The start condition is when a high-to-low transition occurs on the SDA line while SCL is high, as shown in Figure 7-19. All I^2C-compatible devices recognize a start condition.
2. The controller then generates the SCL pulses, and transmits the 7-bit address and the read/write direction bit (R/$\overline{W}$) on the SDA line. During all transmissions, the controller makes sure that data are valid. A valid data condition requires the SDA line to be stable during the entire high period of the clock pulse, as shown in Figure 7-20. All devices recognize the address sent by the controller and compare the address to the respective internal fixed address. Only the target device with a matching address generates an acknowledge by pulling the SDA line low during the entire high period of the 9th SCL cycle, as shown in Figure 7-18. When the controller detects this acknowledge, the communication link with a target has been established.
3. The controller generates further SCL cycles to transmit (R/$\overline{W}$ bit 0) or receive (R/$\overline{W}$ bit 1) data to the target. In either case, the receiver must acknowledge the data sent by the transmitter. The acknowledge signal can be generated by the controller or by the target, depending on which is the receiver. The 9-bit valid data sequences consists of eight data bits and one acknowledge-bit, and can continue as long as necessary.
4. To signal the end of the data transfer, the controller generates a stop condition by pulling the SDA line from low-to-high while the SCL line is high, as shown in Figure 7-19. This action releases the bus and stops the communication link with the addressed target. All I^2C-compatible devices recognize the stop condition. Upon receipt of a stop condition, the bus is released, and all target devices then wait for a start condition followed by a matching address.

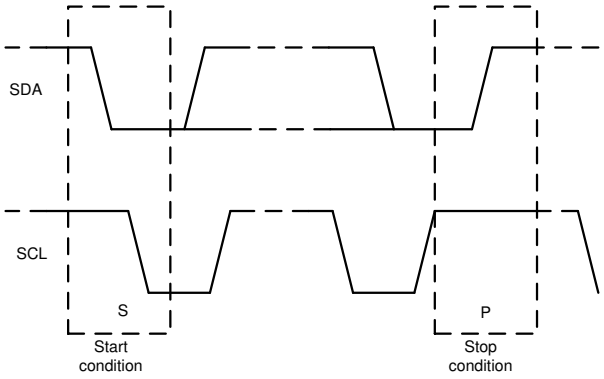

Figure 7-19. Start and Stop Conditions

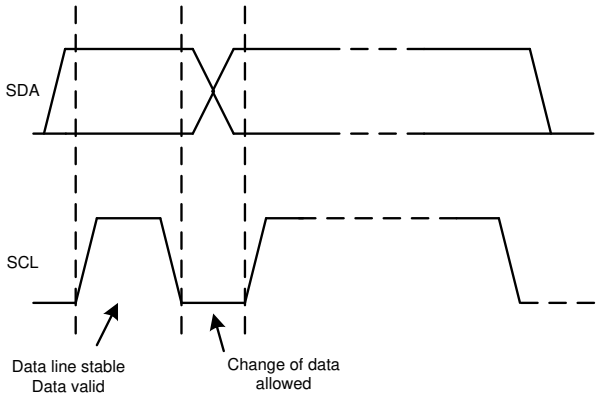

Figure 7-20. Bit Transfer on the I^2C Bus

7.5.2.2 I²C Update Sequence

For a single update, the DACx3204 require a start condition, a valid I²C address byte, a command byte, and two data bytes, as listed in Table 7-14.

Table 7-14. Update Sequence

MSB	....	LSB	ACK	MSB	...	LSB	ACK	MSB	...	LSB	ACK	MSB	...	LSB	ACK
Address (A) byte Section 7.5.2.2.1				Command byte Section 7.5.2.2.2				Data byte - MSDB				Data byte - LSDB			
DB [31:24]				DB [23:16]				DB [15:8]				DB [7:0]			

After each byte is received, the DACx3204 family acknowledges the byte by pulling the SDA line low during the high period of a single clock pulse, as shown in Figure 7-21. These four bytes and acknowledge cycles make up the 36 clock cycles required for a single update to occur. A valid I²C address byte selects the DACx3204.

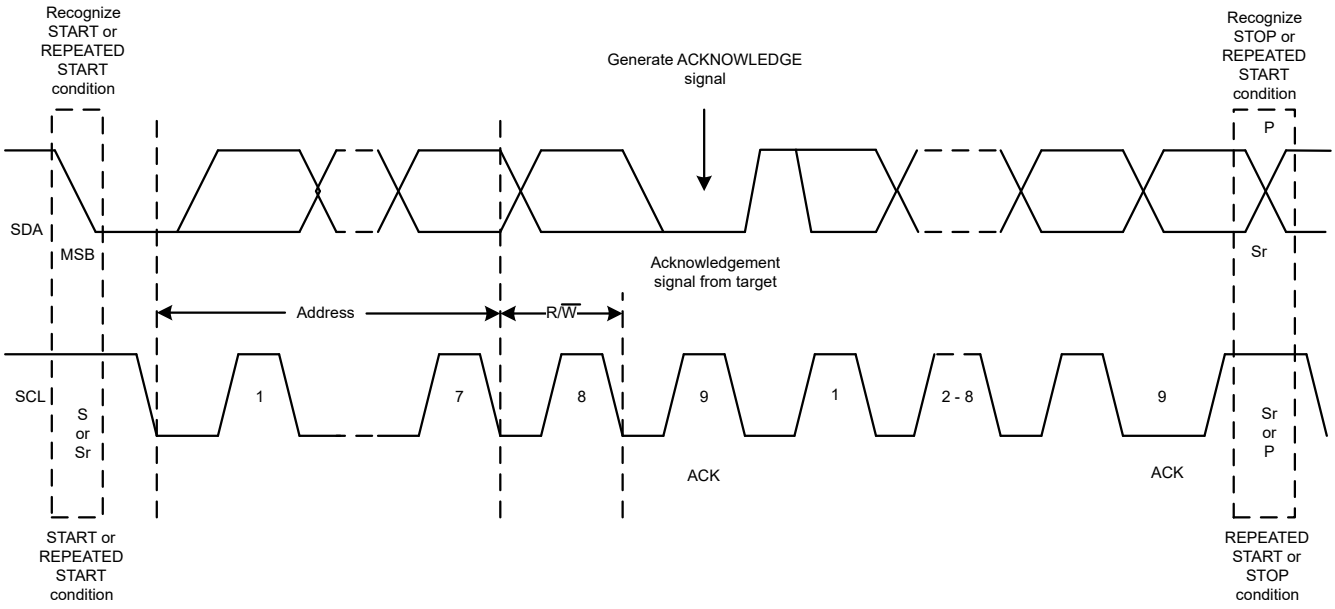

Figure 7-21. I²C Bus Protocol

The command byte sets the operating mode of the selected DACx3204 device. For a data update to occur when the operating mode is selected by this byte, the DACx3204 device must receive two data bytes: the most significant data byte (MSDB) and least significant data byte (LSDB). The DACx3204 device performs an update on the falling edge of the acknowledge signal that follows the LSDB.

When using fast mode (clock = 400 kHz), the maximum DAC update rate is limited to 10 kSPS. Using fast mode plus (clock = 1 MHz), the maximum DAC update rate is limited to 25 kSPS. When a stop condition is received, the DACx3204 device releases the I²C bus and awaits a new start condition.

7.5.2.2.1 Address Byte

The address byte, as shown in Table 7-15, is the first byte received from the controller device following the start condition. The first four bits (MSBs) of the address are factory preset to 1001. The next three bits of the address are controlled by the A0 pin. The A0 pin input can be connected to VDD, AGND, SCL, or SDA. The A0 pin is sampled during the first byte of each data frame to determine the address. The device latches the value of the address pin, and consequently responds to that particular address according to Table 7-16.

Table 7-15. Address Byte

COMMENT	MSB							LSB
—	AD6	AD5	AD4	AD3	AD2	AD1	AD0	R/$\overline{W}$
General address	1	0	0	1	See Table 7-16 (target address column)			0 or 1
Broadcast address	1	0	0	0	1	1	1	0

Table 7-16. Address Format

TARGET ADDRESS	A0 PIN
000	AGND
001	VDD
010	SDA
011	SCL

The DACx3204 supports broadcast addressing, which is used for synchronously updating or powering down multiple DACx3204 devices. When the broadcast address is used, the DACx3204 responds regardless of the address pin state. Broadcast is supported only in write mode.

7.5.2.2.2 Command Byte

Table 7-21 lists the command byte in the ADDRESS column.

Copyright © 2021 Texas Instruments Incorporated

7.5.2.3 I^2C Read Sequence

To read any register the following command sequence must be used:

1. Send a start or repeated start command with a target address and the R/$\overline{W}$ bit set to 0 for writing. The device acknowledges this event.
2. Send a command byte for the register to be read. The device acknowledges this event again.
3. Send a repeated start with the target address and the R/$\overline{W}$ bit set to 1 for reading. The device acknowledges this event.
4. The device writes the MSDB byte of the addressed register. The controller must acknowledge this byte.
5. Finally, the device writes out the LSDB of the register.

The broadcast address cannot be used for reading.

Table 7-17. Read Sequence

S	MSB	…	R/$\overline{W}$ (0)	ACK	MSB	…	LSB	ACK	Sr	MSB	…	R/$\overline{W}$ (1)	ACK	MSB	…	LSB	ACK	MSB	…	LSB	ACK

From Controller				Target	From Controller			Target	From Controller				Target	From Target			Controller	From Target			Controller

7.5.3 General-Purpose Input/Output (GPIO) Modes

Together with I^2C and SPI, the DACx3204 also support a GPIO that can be configured in the NVM for multiple functions. This pin allows for updating the DAC output channels and reading status bits without using the programming interface, thus enabling processor-less operation. In the GPIO-CONFIG register, write 1 to the GPI-EN bit to set the GPIO pin as an input, or write 1 to the GPO-EN bit to set the pin as output. There are global and channel-specific functions mapped to the GPIO pin. For channel-specific functions, select the channels using the GPI-CH-SEL field in the GPIO-CONFIG register. Table 7-18 lists the functional options available for the GPIO as input and Table 7-19 lists the options for the GPIO as output. Some of the GP input operations are edge-triggered after the device boots up. After the power supply ramps up, the device registers the GPI level and executes the associated command. This feature allows the user to configure the initial output state at power-on. By default, the GPIO pin is not mapped to any operation. When the GPIO pin is mapped to a specific input function, the corresponding software bit functionality is disabled to avoid a race condition. When used as a $\overline{\text{RESET}}$ input, the GPIO pin must transmit an active-low pulse for triggering a device reset. All other constraints of the functions are applied to the GPIO-based trigger.

Note

Pull the GPIO pin to high or low when not used. When the GPIO pin is used as $\overline{\text{RESET}}$, the configuration must be programmed into the NVM. Otherwise, the setting is cleared after the device resets.

Table 7-38. GPIO-CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
15	GF-EN	R/$\overline{W}$	0	0: Glitch filter disabled for GP input. This setting provides faster response. 1: Glitch filter enabled for GPI. This setting introduces additional propagation delay but provides robustness.
14	X	X	0	Don't care.
13	GPO-EN	R/$\overline{W}$	0	0: Disable output mode for GPIO pin. 1: Enable output mode for GPIO pin.
12 - 9	GPO-CONFIG	R/$\overline{W}$	0000	$\overline{STATUS}$ function setting. The GPIO pin is mapped to the following register bits as output: 0001: NVM-BUSY 0100: DAC-0-BUSY 0101: DAC-1-BUSY 0110: DAC-2-BUSY 0111: DAC-3-BUSY 1000: WIN-CMP-0 1001: WIN-CMP-1 1010: WIN-CMP-2 1011:WIN-CMP-3 Others: NA

Copyright © 2021 Texas Instruments Incorporated

Table 7-38. GPIO-CONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8 - 5	GPI-CH-SEL	R/W	0000	Each bit corresponds to a DAC channel. 0b is *disabled* and 1b is *enabled*. GPI-CH-SEL[0]: Channel 0 GPI-CH-SEL[1]: Channel 1 GPI-CH-SEL[2]: Channel 2 GPI-CH-SEL[3]: Channel 3 Example: when GPI-CH-SEL is 0101, both channel-0 and channel-2 are enabled and both channel-1 and channel-3 are disabled.
4 - 1	GPI-CONFIG	R/W	0000	GPIO pin input configuration. Global settings act on the entire device. Channel-specific settings are dependent on the channel selection by the GPI-CH-SEL bits: 0010: $\overline{\text{FAULT-DUMP}}$ (global). GPIO falling edge triggers fault dump, GPIO = 1 has no effect. 0011: IOUT power up-down (channel-specific). GPIO falling edge triggers power down, GPIO rising edge triggers power up. 0100: VOUT power up-down (channel-specific). The output load is as per the VOUT-PDN-X setting. GPIO falling edge triggers $\overline{\text{ECT}}$ input (global). GPIO falling edge asserts $\overline{\text{PROTECT}}$ function, GPIO = 1 has no effect. 0111: $\overline{\text{CLR}}$ input (global). GPIO = 0 asserts $\overline{\text{CLR}}$ function, GPIO = 1 has no effect. 1000: $\overline{\text{LDAC}}$ input (channel-specific). GPIO falling edge asserts $\overline{\text{LDAC}}$ function, GPIO = 1 has no effect. Both the SYNC-CONFIG-X and the GPI-CH-SEL must be configured for every channel. 1001: Start and stop function generation (channel-specific). GPIO falling edge stops function generation. GPIO rising edge starts function generation. 1010: Trigger margin high-low (channel-specific). GPIO falling edge triggers margin low. GPIO rising edge triggers margin high. 1011: $\overline{\text{RESET}}$ input (global). The falling edge of the GPIO pin asserts the $\overline{\text{RESET}}$ function. The $\overline{\text{RESET}}$ input must be a pulse. The GPIO rising edge brings the device out of reset. The $\overline{\text{RESET}}$ configuration must be programmed into the NVM. Otherwise the setting is cleared after the device reset. 1100: NVM write protection (global). GPIO falling edge allows NVM programming. GPIO rising edge blocks NVM programming. 1101: Register-map lock (global). GPIO falling edge allows update to the register map. GPIO rising edge blocks any register map update except a write to the DEV-UNLOCK field through I^2C or SPI and to the RESET field through I^2C. Others: Invalid
0	GPI-EN	R/W	0	0: Disable input mode for GPIO pin. 1: Enable input mode for GPIO pin.

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

The DACx3204 are quad-channel buffered, force-sense output, voltage-output and current-output smart DACs that include an NVM and internal reference, and available in a tiny 3-mm × 3-mm package. In voltage-output mode, short the OUTx and FBx pins for each channel. In current-output mode, leave the FBx pins unconnected. The FBx pins function as inputs in comparator mode. The external reference must not exceed VDD, either during transient or steady-state conditions. For the best Hi-Z output performance, use a pullup resistor on the VREF pin to VDD. In case the VDD remains floating during the off condition, place a 100-kΩ resistor to AGND for proper detection of the VDD off condition. All the digital outputs are open drain; use external pullup resistors on these pins. The interface protocol is detected at power-on, and the device locks to the protocol as long as VDD is on. In I^2C mode, when allocating the I^2C addresses in the system, consider the broadcast address as well. I^2C timeout can be enabled for robustness. SPI mode is 3-wire by default. Configure the GPIO pin as SDO in the NVM for SPI readback capability. The SPI clock speed in readback mode is slower than that in write mode. Power-down mode sets the DAC outputs in Hi-Z by default. Change the configuration appropriately for different power-down settings. The DAC channels can also power-up with a programmed DAC code in the NVM.

8.2 Typical Application

A power-supply margining and scaling circuit is used to trim, scale, or test the output of a power converter. This example circuit is used to test a system by margining the power supplies for adaptive voltage scaling or to program a desired value at the output. Adjustable power supplies, such as low-dropout regulators (LDOs) and DC/DC converters, provide a feedback or adjust the input that is used to set the desired output. A precision voltage-output DAC is the best choice for controlling the power-supply output linearly. Figure 8-1 shows a control circuit for a switch-mode power supply (SMPS) using the DACx3204. Typical applications of power-supply margining are communications equipment, enterprise servers, test and measurement, and general-purpose power-supply modules.

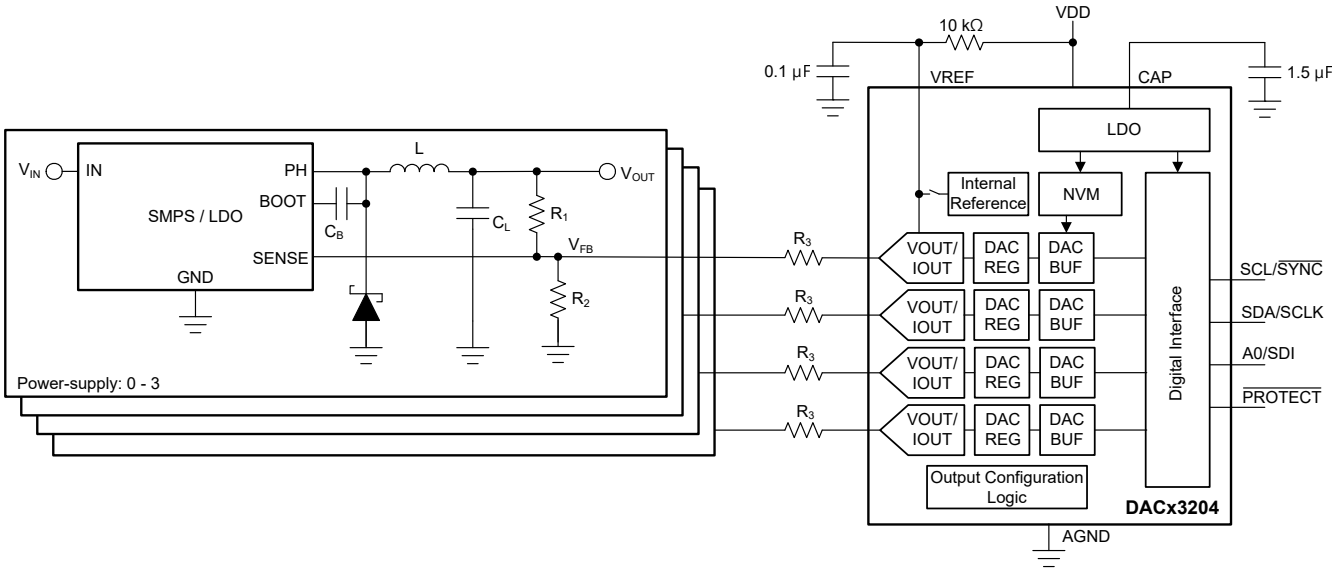

Figure 8-1. Voltage Margining and Scaling

8.2.1 Design Requirements

Table 8-1. Design Parameters

PARAMETER	VALUE
Power-supply nominal output	3.3 V
Reference voltage of the converter (V_{FB})	0.6 V
Margin	±10% (that is, 2.97 V to 3.63 V)
DAC output range	1.8 V
Nominal current through R_1 and R_2	100 µA

8.2.2 Detailed Design Procedure

The DACx3204 features a Hi-Z power-down mode that is set by default at power-up, unless the device is programmed otherwise using the NVM. When the DAC output is at Hi-Z, the current through R_3 is zero and the SMPS is set at the nominal output voltage of 3.3 V. To have the same nominal condition when the DAC powers up, bring up the device at the same output as V_{FB} (that is 0.6 V). This configuration makes sure there is no current through R_3 even at power-up. Calculate R_1 as (V_{OUT} – V_{FB}) / 100 µA = 27 kΩ.

To achieve ±10% margin-high and margin-low conditions, the DAC must sink or source additional current through R_1. Calculate the current from the DAC (I_{MARGIN}) using Equation 9 as 12 µA.

$$I_{MARGIN} = \left(\frac{V_{OUT} \times (1 + MARGIN) - V_{FB}}{R_1}\right) - I_{NOMINAL} \quad (9)$$

where

- I_{MARGIN} is the margin current sourced or sinked from the DAC.
- MARGIN is the percentage margin value divided by 100.
- $I_{NOMINAL}$ is the nominal current through R_1 and R_2.

To calculate the value of R_3, first decide the DAC output range, and make sure to avoid the codes near zero-scale and full-scale for safe operation in the linear region. A DAC output of 20 mV is a safe consideration as the minimum output, and (1.8 V – 0.6 V – 20 mV = 1.18 V) as the maximum output. When the DAC output is at 20 mV, the power supply goes to margin high, and when the DAC output is at 1.18 V, the power supply goes to margin low. Calculate the value of R_3 using Equation 10 as 48.3 kΩ. Choose a standard resistor value and adjust the DAC outputs. Choosing R_3 = 47 kΩ makes the DAC margin high code as 1.164 V and the DAC margin low code as 36 mV.

$$R_3 = \frac{|V_{DAC} - V_{FB}|}{I_{MARGIN}} \quad (10)$$

When the DACx3204 are set in the current-output mode, the series resistor R_3 is not required. Set the DAC output at the current-output range of –25 µA to +25 µA, and set the DAC code appropriately to achieve a margin current of ±12 µA.

The DACx3204 have a slew-rate feature that is used to toggle between margin high, margin low, and nominal outputs with a defined slew rate. See Section 7.6.7 for the slew-rate setting details.

Note

The DAC-X-MARGIN-HIGH register value in DACx3204 results in the *margin-low* value at the power supply output. Similarly, the DAC-X-MARGIN-LOW register value in DACx3204 results in the *margin-high* value at the power-supply output.

The pseudocode for getting started with a power-supply control application is as follows:

```
//SYNTAX: WRITE <REGISTER NAME (Hex code)>, <MSB DATA>, <LSB DATA>
//Write DAC code for nominal output (repeat for all DAC channels)
//For a 1.8-V output range, the 10-bit hex code for 0.6 V is 0x155. With 16-bit left alignment,
this becomes 0x5540
WRITE DAC_DATA(0x19), 0x55, 0x40
//Power-up voltage output on all channels, enables internal reference WRITE COMMON-CONFIG(0x1F),
0x12, 0x49
//Set channel 0 gain setting to 1.5x internal reference (1.8 V)
WRITE DAC-0-VOUT-CMP-CONFIG(0x3), 0x08, 0x00
//Set channel 1 gain setting to 1.5x internal reference (1.8 V)
WRITE DAC-1-VOUT-CMP-CONFIG(0x9), 0x08, 0x00
//Set channel 2 gain setting to 1.5x internal reference (1.8 V)
WRITE DAC-2-VOUT-CMP-CONFIG(0xF), 0x08, 0x00
//Set channel 3 gain setting to 1.5x internal reference (1.8 V)
WRITE DAC-3-VOUT-CMP-CONFIG(0x15), 0x08, 0x00
//Configure GPI for Margin-High, Low trigger for all channels
WRITE GPIO-CONFIG(0x24), 0x01, 0xF5
//Set slew rate and code step (repeat for all channels)
//CODE_STEP: 2 LSB, SLEW_RATE: 60.72 µs/step
WRITE DAC-0-FUNC-CONFIG(0x06), 0x00, 0x17
//Write DAC margin high code (repeat for all channels)
//For a 1.8-V output range, the 10-bit hex code for 1.164 V is 0x296. With 16-bit left alignment,
this becomes 0xA540
WRITE DAC-0-MARGIN-HIGH(0x01), 0xA5, 0x40
//Write DAC margin low code (repeat for all channels)
//For a 1.8-V output range, the 10-bit hex code for 36 mV is 0x14. With 16-bit left alignment, this
becomes 0x0500
WRITE DAC-0-MARGIN-LOW(0x02), 0x05, 0x00
//Save settings to NVM
WRITE COMMON-TRIGGER(0x20), 0x00, 0x02
```

8.2.3 Application Curves

9 Power Supply Recommendations

The DACx3204 family of devices does not require specific power-supply sequencing. These devices require a single power supply, V_{DD}. However, make sure the external voltage reference is applied after VDD. Use a 0.1-µF decoupling capacitor for the V_{DD} pin. Use a bypass capacitor with a value approximately 1.5 µF for the CAP pin.

10 Layout

10.1 Layout Guidelines

The DACx3204 pin configuration separates the analog, digital, and power pins for an optimized layout. For signal integrity, separate the digital and analog traces, and place decoupling capacitors close to the device pins.

10.2 Layout Example

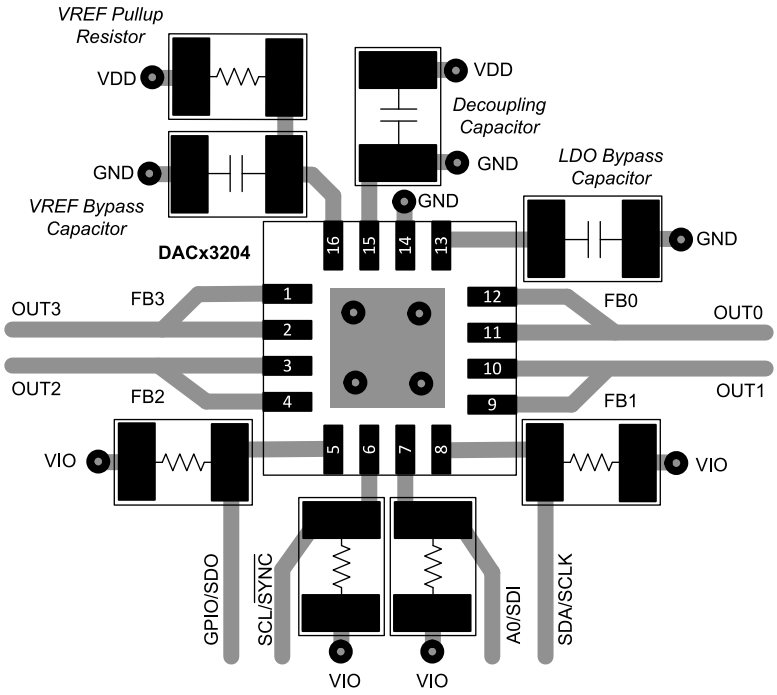

Figure 10-1. Layout Example

Note: The ground and power planes have been omitted for clarity. Connect the thermal pad to ground.

11 Device and Documentation Support

TI offers an extensive line of development tools. Tools and software to evaluate the performance of the device, generate code, and develop solutions are listed below.

11.1 Documentation Support

11.1.1 Related Documentation

The following EVM user's guide is available: *DACx3204 Evaluation Module* user's guide

11.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. Click on *Subscribe to updates* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

11.3 Support Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

11.4 Trademarks

PMBus™ is a trademark of SMIF, Inc..
TI E2E™ is a trademark of Texas Instruments.
All trademarks are the property of their respective owners.

11.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

11.6 Glossary

TI Glossary — This glossary lists and explains terms, acronyms, and definitions.

12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

85% PRINTED SOLDER COVERAGE BY AREA UNDER PACKAGE
SCALE:25X

4219117/B 04/2022

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATASHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES “AS IS” AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you fully indemnify TI and its representatives against any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI’s products are provided subject to TI’s Terms of Sale, TI’s General Quality Guidelines, or other applicable terms available either on ti.com or provided in conjunction with such TI products. TI’s provision of these resources does not expand or otherwise alter TI’s applicable warranties or warranty disclaimers for TI products. Unless TI explicitly designates a product as custom or customer-specified, TI products are standard, catalog, general purpose devices.

TI objects to and rejects any additional or different terms you may propose.
